THE USE OF RATIO CONCEPTUAL COST ESTIMATION FOR PETROCHEMICAL CONSTRUCTION PROJECTS IN SOUTH AFRICA

by

WILLEM PETRUS SMITH

submitted in accordance with the requirements for the degree of

PHILOSOPHIAE DOCTOR

in the

FACULTY OF NATURAL SCIENCES

DEPARTMENT OF QUANTITY SURVEYING AND CONSTRUCTION MANAGEMENT

at the

UNIVERSITY OF THE FREE STATE

2011

PROMOTER: PROF. H. J. MARX

(Volume 1 of 3)

"It is the mark of an educated mind to rest satisfied with the degree of precision which the nature of the subject admits and not to seek exactness where only an approximation is possible"

- Aristotle

SYNOPSIS

The fast pace in which construction projects are being executed and the fact that almost all green field projects in the petrochemical industry are constructed by means of "fast-track" methodologies, has the effect that financial management becomes increasingly difficult. The congested construction program together with the increased emphasis on accurate financial reporting, created an opportunity to improve forecasting methods without spending too much time on such exercises.

In my personal capacity, I found the current typical procedure of allowing for additional scope of work, inadequate. The time allocated to come up with estimated costs for new scope / additional scope does not allow for comprehensive measurements to conduct detailed estimates. The only alternative was therefore to find other means of obtaining fairly accurate estimated costs for proposed new scopes of work.

Construction time will not be increased to allow for exercises like these, in fact, future construction periods will rather decrease, which will lead to a compounding effect of the problem. To me the only solution is to employ an estimating method that has proofed itself in the industry over many years. The quickest estimating methods are the conceptual estimates of which ratio conceptual estimating will probably take the least time. The downside of this form of estimating is that it is also not as accurate as detailed estimates, but if it is based on good historical data, one can get good results that will be more than adequate for this purpose.

My discussions with clients and other professionals in the field over the past couple of years reiterated the urgency of an improved financial forecasting procedure, especially when dealing with larger additions to the scope of work. Should ratio conceptual estimating be used, it must be clearly understood that this form of estimating is very dependable on the accuracy of the database on which it is based. A significant effort should be instilled in deriving at a good quality database. This takes a lot of time and it will not come cheap, but the benefit of this investment will be realized in future projects and will increase as the number of newly finished projects are added to the database.

OPSOMMING

Die vinnige tempo waarteen konstruksie projekte uitgevoer word en die feit dat feitlik alle nuwe projekte in die petro-chemiese industrie gebou word deur gebruik te maak van versnelde metodes; het die effek dat finansiële bestuur al hoe moeiliker raak. Die beperkte tyd in die konstruksie program saam met die toenemende fokus op akkurate finansiële verslaggewing, skep ´n geleentheid om die vooruitskattingsmetodes aan te pas sonder dat daar teveel tyd daaraan spandeer word.

Die huidige tipiese metode vir die toelating vir addisionele werk is ontoereikend. Die beperkte tyd vir die toelating vir addisionele kostes vir nuwe werk laat nie toe vir uitgebreide meetwerk nie. Die enigste alternatief was om kosteberamings met redelike akkuraatheid te ontwikkel.

Konstruksietyd sal nie verleng word om toe te laat vir meer akkurate kosteberamings nie; inteendeel, toekomstige konstruksie periodes sal eerder verkort, wat sal lei tot ´n ontoereikende proses. ´n Moontlike oplossing is om gebruik te maak van ´n beproefde kosteberamingsmetode wat bewys het om betroubaar te wees in die industrie oor etlike jare. Die vinnigste kosteberamingsmetodes is die verkorte metodes waarvan die metode gebaseer op wiskundige verhoudings, sekerlik die minste tyd sal neem. Die nadeel van hierdie vorm van kosteberaming is dat dit minder akkuraat is as gedetailleerde metodes, maar goeie resultate kan verkry word indien dit gebaseer is op ´n goeie databasis.

Onderhoude met kliënte en ander professionele persone in die bedryf gedurende die afgelope paar het die dringendheid van ´n verbeterde finansiële vooruitskattingsprosedure; veral in die geval van groot toevoegings tot die projek, beklemtoon. Die ontwikkeling van ´n databasis sal baie tyd in beslag neem en duur wees, maar die voordeel daarvan sal in die toekoms ervaar word. Hoe meer data van voltooide projekte tot die databasis toegevoeg word, hoe akkurater sal die inligting wees wat onttrek word.

ACKNOWLEDGEMENTS

I wish to express my appreciation to the following persons and institutions:

- To my heavenly Father for the grace and strength to walk this road to its completion.
- To Prof. H. J. Marx and Prof. J. J. P. Verster for acting as promoter and co-promoter for this thesis, and for the privilege of studying under their guidance for the past years.
- To my family: Shantèl, Erich, Delarey and Liami, for accepting hardship and tolerating me over the many years of study.
- To my parents for providing me with many opportunities, and for their support.
- To the University of the Free State (the Department of Quantity Surveying and Construction Management in particular) for their support throughout the duration of the study.
- To the competent staff of Broca media and language consultants for editing the manuscript of this thesis. The responsibility for errors that remain is mine.
- To all my colleagues at Thyssenkrupp PDNA Engineering for their support with the study.

DECLARATION

I, Willem Petrus Smith, herewith declare that this thesis for the degree PHILOSOPHIAE DOCTOR, represents my own independent work and that I have not previously submitted the same work for a qualification at / in another University / Faculty. I also hereby cede copyright of this thesis to the University of the Free State.

November 2011

CHAPTER 1

INTRODUCTION AND BACKGROUND TO THE STUDY

1.0 INTRODUCTION

Systematic capital cost engineering and capital cost estimating have developed into a specialist activity (Hollmann, 2007b: 8), although Brook (2004: 66) indicates that the core essentials of estimating have remained the same since the first half of the twentieth century. Estimating has been described as both an art and a science. This distinction is mainly due to the constant studies of costs and trends (Hughes, 1991: 3), analysing the results, and recording it (Zastrozny, 1974: 4). Cost estimation is the foundation for economic analysis in construction (Newman, Eschenbach & Lavelle, 2004: 38). Once sufficient data has been collected and processed it should be converted into methods and systems that then become suitable tools for producing realistic capital cost budgets.

Costing of certain elements is an essential part of construction (Newman, *et al.*, 2004: 38). It can take on several forms and can be used for several purposes (Cesarone, 2007: 37). Cost determination or cost estimating should form part of any construction project (Brook, 2004: 66). From the initial stages to the very end, costing can assist management in various forms (Azhar, Ahmed & Caballero, n.d.: 1).

Realistic estimates are essential (Dysert, 2004: 9.1). An over-estimate may cause a promising proposition to be abandoned whereas an under-estimate may result in financial losses. There are many benefits derived from the use of estimates apart from being able to predict the probable cost of capital projects (Black, 1984: 59; Humphreys, 1984: 52).

First and foremost it is used as a basis for economic studies (Humphreys, 1984: 52) to determine the profitability of the manufacturing of a proposed product (Clark & Lorenzoni, 1985: 24). Once an economic study has proved favourable and it has been decided to proceed with the actual construction, the estimate gains even more in importance.

Eventually the estimate becomes a tool for manpower planning, time scheduling, and finance planning (Hollmann, 2007b: 8). By making cost comparisons possible the estimate also assists the decision-making authority in accepting or rejecting tenders from contractors. During the actual construction period the estimate becomes a powerful implement in the application of cost control and financial forecasting (Dysert, 2004: 9.1).

The orderly execution of a capital project will, apart from effecting many savings, facilitate the introduction of an efficient cost feedback system and eventually provide a proper cost history (Tompkins, 1985: 4); both of which are essential to the preparation and improvement of future estimates (Dysert, 2004: 9.8).

The capturing of actual cost on completion of a project is the beginning of a cost history (Bent, 1982: 13), which if properly utilised becomes the main source of information for the development of efficient short cut estimating methods (Zastrozny, 1974: 4). An essential requirement is the early establishment of records covering as wide a range as possible of materials, equipment and labour costs (Zastrozny, 1974: 4). These must be brought up to date regularly and extended as new information becomes available (Dysert, 2004: 9.5).

A cost feedback system must be in place (Bent, 1982: 13-14). This system should collect all actual cost data and interrelationships between various types of data must be established (Black, 1984: 59). Dysert and Pickett (2005: 30) indicate that this will allow the determination of reliable factors for the use in ratio conceptual cost estimating. On completion of a project the total actual cost must similarly be incorporated in the costing data. This cost history, if properly utilised, becomes the main source of information for the development of efficient short cut estimating methods (Kwak & Watson, 2005: 1430).

The most important single requirement for obtaining a reasonably accurate estimate is the information supplied to the estimator by other parties. Liu and Zhu (2007: 91) point out that detailed information is seldom available at the estimate stage. The estimator should therefore work closely with the engineering team to be included in all decisions on the design. Zastrozny (1974: 4) states that the best estimate information originates from engineers that worked in closely with the estimating group over long periods.

The importance of cost history cannot be overemphasized, however, there are also other factors which can have an effect on the accuracy of an estimate. The time value of money (escalation) (Opfer, 2004: 7.3; Humphreys, 1984: 159) and competency of staff members (Molenaar, 2005: 343) also have a significant effect on the accuracy of estimates. Cost is the value of an activity or asset (Postula, 2004: 1.1). Cost estimating is not an exact science and allowances within the estimate are often based on assumptions (Azhar, *et al.*, n.d.:1). The estimator must, however, always be able to explain his rationale in his decision-making and why he chose to make certain assumptions.

The use of cost estimating principles can be a handy tool in financial forecasting (Dysert, 2004: 9.32). Dysert and Pickett (2005: 30) and Kwak and Watson (2005: 1430) state that in the beginning of the project when there are various unknown factors or non-definitive designs, conceptual cost estimating can be applied to determine more accurate estimated final costs. As the project progresses and designs become more definitive, conceptual cost estimating can be used to test measurements and allowances (Clark & Lorenzoni, 1985: 31). There are always a number of additions on any project. The cost for these additions can in most cases also be calculated by using conceptual cost estimating.

2.0 TITLE

Ratio conceptual cost estimating in South African petrochemical construction projects.

3.0 PROBLEM STATEMENT

Over the years cost control has evolved into a fine art and a specialist practice. Organisations have cost control systems in place during the construction phase and have good estimating methods when tendering for new work.

One of the tools that have been developed to assist management in decision-making is the financial review (financial forecast). In essence, this is a basic estimate of what the final cost on a particular project will be. This forecast is adjusted as the project nears completion and should eventually equal the final account value.

During the course of any project there will, however, be additions and omissions to the scope of work. The client might require more scope or improved design on existing scope, or might decide to omit certain scope. The organisation employed by the client to construct the project might also become aware of certain changes to the scope of work. These changes will necessitate updates to the Estimated Final Cost (EFC).

It appears that these changes are in most cases influenced by a gut feel of what the cost will be, rather than a more scientific approach. One way of improving this form of forecasting is to employ known estimating methods which are well tested. Ratio Conceptual Cost Estimating (RCE) is one such method. This method is a quick form of estimating based on historical data. The incorporation of such a method will improve the way in which financial forecasting is done.

4.0 PRIMARY OBJECTIVE

The primary objective of this study is to prove the effectiveness of Ratio Conceptual Cost Estimating (RCE) in the South African petrochemical construction industry.

5.0 SECONDARY OBJECTIVE

Should the Primary Objective be accomplished, the researcher might be able to proof the value of Ratio Conceptual Cost Estimating (RCE) during the construction phase of the project as well, i.e. the financial forecast.

6.0 HYPOTHESIS

6.1 Primary hypothesis

It is possible to apply Ratio Conceptual Cost Estimating (RCE) in the South African petrochemical construction industry.

6.2 Secondary hypothesis

The use of Ratio Conceptual Cost Estimating (RCE) in the construction of South African petrochemical projects will lead to improved cost forecasting.

7.0 RESTRICTIONS

The design, development, and ultimately the construction of a petrochemical plant is a complex process that expands on a multi-disciplinary level, which in itself makes it difficult to complete a design before the plant is 100% constructed. Minor changes will occur throughout the development of the plant, and especially when the new plant needs to tie into the current factory grid, there will be unknowns to the engineers that will only be realised once the physical work gets done on site. These initial unknowns might influence pipe sizes, cable sizes, material types, etc. It is because of this reason, as well as the fact that brown field work never stands in correlation to the brown field work on the next project, that all costs relating to work of this type has been omitted from this study.

The material cost of items such as piping and piping equipment as well as mechanical equipment fluctuate to such an extent that to include these materials and equipment in the ratio conceptual cost estimating process will be dangerous. This is not really the case in countries where many similar and often identical plants are constructed, but in Southern Africa there are a limited number of new plants erected. This limited source of information makes it risky to include the volatile cost of piping material and mechanical equipment and therefore the cost of these materials have been omitted from this study.

Petrochemical plants are constructed by the private sector and because of the highly competitive nature of the industry most details pertaining to any given plant are treated as confidential. Obtaining information/data is therefore problematic and in most cases databases and procedures will evolve as the estimator’s level of experience increases.

8.0 DEFINITIONS

- **Profit**: Profit is the amount included in a contractor's price to compensate the contractor for undertaking the risks associated with the project and to provide a return on investment, (Kraus', 2007: EST.18.2).
- **Cost**: Cost is an outflow of a resource, whether in cash, as a payable, a rendered service, or a trade or barter that is consciously made with expectation of benefit to the organisation: goods, property, or service required, (Stenzel & Stenzel, 2003: 2).
- **Cost control**: Cost control is a process to hold expenditures within budget by monitoring and appraisal of the cost performance, (Azhar, Ahmed and Caballero, n.d.: 1).
- **Direct cost**: A direct cost is any cost that can be identified specifically with a final cost objective, (Norfleet, 2007: EST.12.1).
- **Indirect costs**: Indirect costs are those resources that need to be expended to support the activity, but which are also associated with other activities, (Eldenburg & Wolcott, 2005: 38).
- **Overhead cost**: This is a form of indirect cost in its broadest sense in that it cannot be assigned to a specific contract without some method of allocation, (Enshassi, Aziz & Karriri, 2008: 36).
- **Cost management**: Cost management is the use of cost accounting systems and methods to guide current and future operations towards specified objectives; the analysis and interpretation of cost data is critical to the decision-making process, (Stenzel & Stenzel, 2003: 3).
- **Cost trending**: Trending is a project cost and schedule control technique used continuously through all stages of a project to illustrate deviations from the control budget or project schedule, (Tompkins, 1985: 20).
- **Productivity**: Productivity is the ratio of some measurable unit of output to some unit of input. Productivity is therefore a measure of efficiency, or the amount of work that the employees complete during each working day, (Carrell, Kuzmits & Elbert, 1989: 74).
- **Performance**: Performance is the realising of goals,agreed upon or set by the individual for himself, and meeting his own expectations or those of other

people, such as managers or colleagues, to whom a product is delivered or to whom a service is rendered, (Coetsee, 2002: 7).

- **Rework**: Rework is the process by which an item is made to conform to the original requirement by completion or correction, (Ashford, 1992: 12).
- **Work breakdown structure (WBS)**: A work breakdown structure (WBS) is a deliverables-orientated decomposition of the project. It is not the activities needed to create the project deliverables; it is the outcome that the activities create, (Phillips, 2005).
- **Work package**: A work package is a well-defined scope of work that terminates in a deliverable product(s) or completion of a service. Each package may vary in size, but each must be a measurable and controllable unit of work to be performed, (Humphreys, 1991: 471).
- **Estimate**: An estimate is a prediction of quantities, cost and/or resources required by the scope of an asset investment option, activity or project. As a prediction, an estimate must address risks and uncertainties, (Dysert, 2004: 9.27).
- **Database**: A collection of actual historical project data with special emphasis on quantities and cost data; normalised into useful compatible data and expressed as ratios of each other, (Pickett & Elliot, 2007: EST.02.1).
- **Inflation**: Inflation may be defined as an increase in the general price level for goods and services occurring over a relatively brief period of time, (Faig & Jerez, 2006: 3).
- **Escalation**: Escalation is the effect between the interplay of changes, real or anticipated, in input costs, perceptions of risk, and perceptions of the competition. Escalation occurs due to changes in price levels driven by underlying economic conditions, (Hollmann and Dysert, 2008: EST.08.1).
- **Contingency**: Contingency is defined as the amount to be added to the competitive base estimate, prepared realistically for the known scope assuming typical site/market conditions/oversights/unknowns, and is free of excessive allowances and mark-ups as per historical experience so that the final project cost estimate has an equal chance of falling above/below the actual cost or the initial quantifiable estimate, (Skitmore & Ng, 2002: 457).

- **Estimated final cost**: An estimated final cost is a collection of historical, current and estimated future costs on a project, (Shirley and Banks, 2007: EST.11.1).
- **Cost forecasting**: Cost forecasting is the process in which estimated values are put to future costs on a project to predict the end value of the project, (Brigham, Gapenski & Daves, 1999: 243).
- **Scope of work**: Total work to be accomplished and administrative requirements associated with a contract as described within the contract documents, which may include the general conditions, special conditions, specifications, drawings and addenda, (Humphreys, 1991: 367).

9.0 RESEARCH METHODOLOGY

Leedy (1980: 119) describes various approaches to the methodology of a thesis. These approaches were studied in order to identify the correct methodology to be used in order to support the problem statement and the sub-problems to the research being addressed.

According to Leedy (1980: 119), the historical method of research is the means by which the researcher deals with the latent meaning of history. The object of the historical method, therefore, is to provide a means through which the researcher may deal with problems that arise from the events that happened in times past and to interpret what might otherwise be considered merely as the happenstance of blind fortune.

Leedy and Ormond (2001: 70) state that the literature review describes theoretical perspectives and previous research findings related to the problem at hand. Its function is to “look again” at what others have done in areas that are similar, though not necessarily identical, to one’s own area of investigation. A researcher should know the literature relating to the topic very well.

The research methodology for this study comprises of:

- A literature survey analysing historical information that has led to the development and implementation of the model.

- Reporting on data gathered from 45 historical projects as well as the normalisation of such data to be expressed as ratios in a database.
- Comparing the normalised data against actual data gathered from 10 completed projects.

9.1 Literature review

The investigation into the problem and sub-problems leads to an extensive literature review. Historical tendencies relating to important aspects surrounding the study and opinions from other related sciences have been thoroughly investigated. The following sources have been consulted:

- Books
- Journal and newspaper articles
- Theses
- Electronic data in the form of articles
- Conference papers

The literature review forms an integrated part of the study since the concept of Ratio Conceptual Cost Estimating (RCE) and financial forecasting primarily has a theoretical build-up. A proper theoretical pre-study therefore was unavoidable.

Although there is sufficient literature on RCE and financial forecasting in general, no literature could be found that deals specifically with the implementation of RCE in financial forecasting to enhance the accuracy and presentation of the financial reporting procedure.

9.2 Data collection

Data from several historical projects was collected and analysed. This data includes actual historical quantities and rates from previous projects upon final agreement. The details of the projects could not be revealed due to secrecy agreements. This data was normalised to make the data compatible with other data. It was then transferred to a database in the form of quantity ratios and rate ratios. These ratios were then employed

by multiplying them with some project base information to determine the quantities and rates of projects or portions of projects with incomplete design and specifications.

10.0 STRUCTURE OF THE THESIS

The structure of the thesis is illustrated in Figure 1.1. After this introductory chapter, the influences on construction cost and the process of construction estimating is investigated. Chapters 2 and 3 describe both these concepts. The methodology of Ratio Conceptual Cost Estimating (RCE) is described in Chapter 4. Chapter 5 describes the establishment of an estimating database and what is necessary to make such a database an invaluable tool when conducting a RCE. Chapter 6 describes the reasons why inflation occurs and the effect thereof on the construction industry. The ultimate effect of inflation on construction is construction price escalation and this phenomenon also is discussed in this chapter. Chapter 7 explains the importance of time in construction and how time can influence the construction schedule. Chapter 8 deals with the practical application of RCE in the petrochemical industry in South Africa and also describes the development of a model to be used in RCE. The conclusion and recommendations is presented in Chapter 9.

Several addendums provide details on estimates and financial forecasts. They are:

Addendum A – Estimating checklist for capital projects
Addendum B – Estimate summary worksheet
Addendum C – Typical work unit sheet
Addendum D – Database for 45 historical projects
Addendum E – Typical financial forecast summary
Addendum F – Summary of Ratio Conceptual Cost Estimate (RCE)
Addendum G - Database for statistically adjusted ratios and RCE's for ten target projects
Addendum H - A typical scope definition breakdown of a portion of a specific project
Addendum I – Estimate stakeholder scope agreement

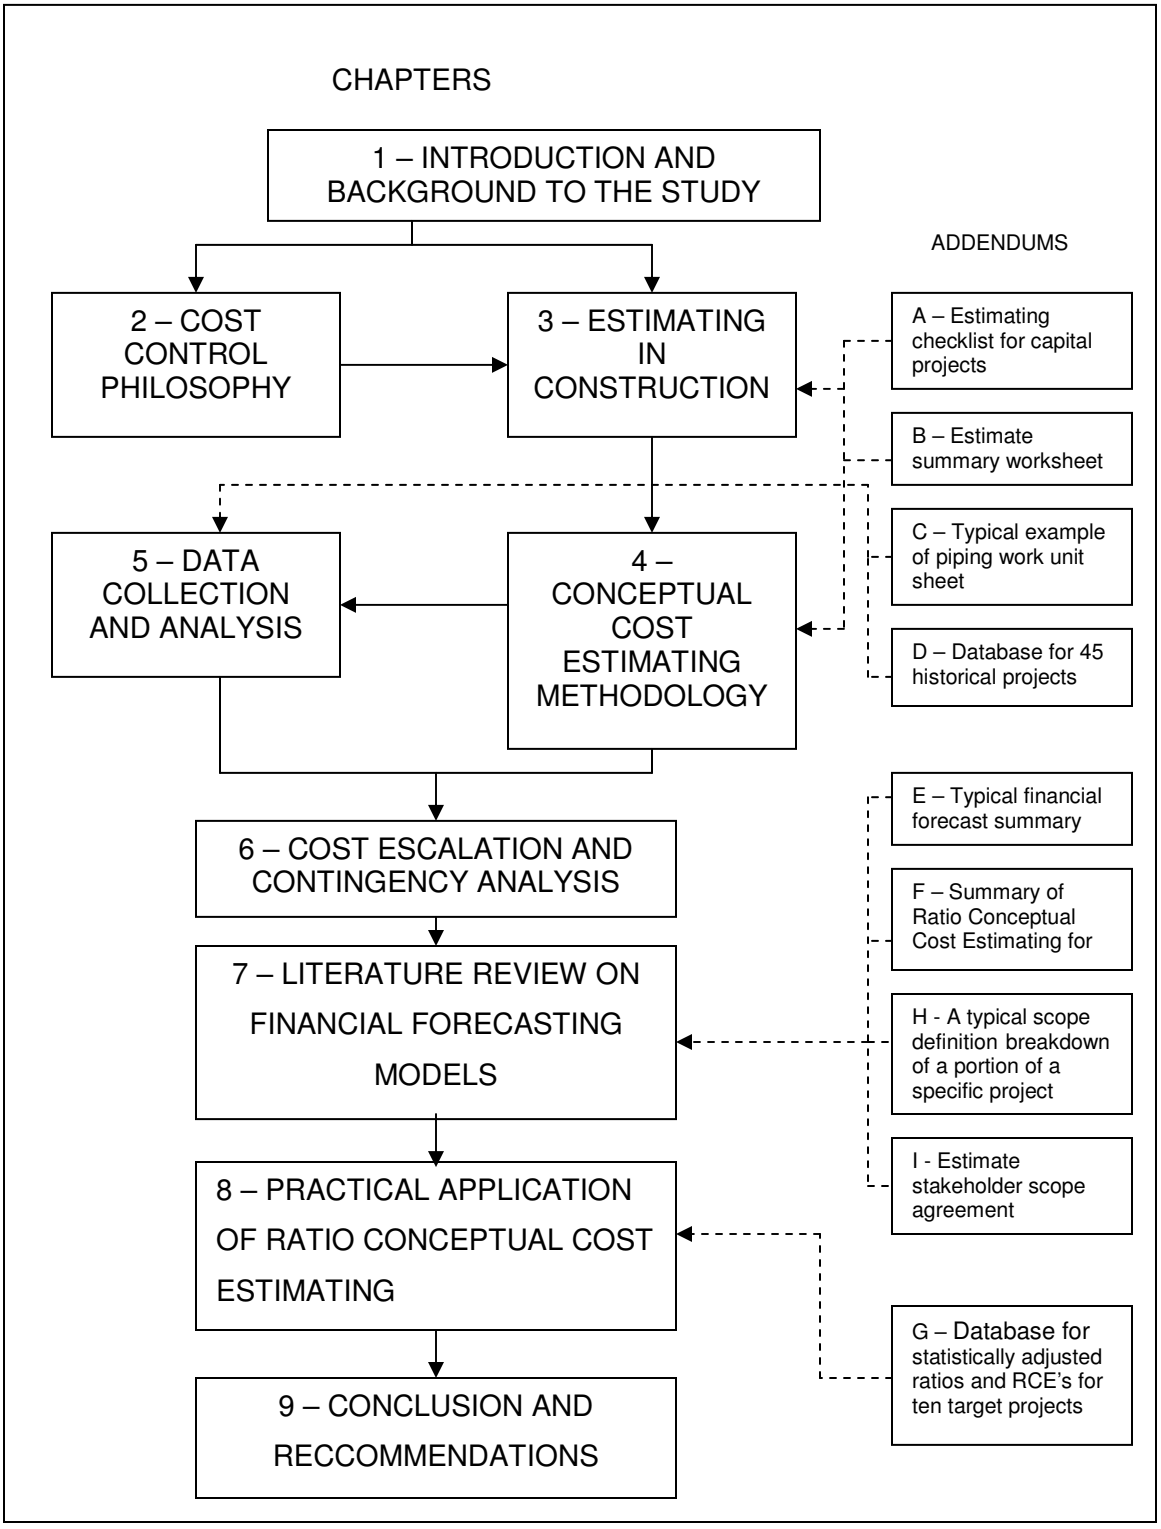

Figure 1.1 Structure of the thesis

The content of each chapter will be described in more detail:

Chapter 2 defines cost control philosophy. This process is started by briefly mentioning some historically significant projects and then connecting modern cost control to lessons learned from these historical projects. The concept of profit is discussed and how different cost types can influence the profit margin of any construction endeavor. These costs are broken down into several sub-divisions such as direct and indirect costs, which in turn are divided into other groups such as material and labour. Secondary aspects such as productivity and its effects are mentioned. Lastly, engineering is discussed to emphasise the importance thereof in making the project a success.

Chapter 3 describes the process of cost estimating in construction with special emphasis on estimating in the engineering field, and more specifically, the petrochemical field. The requirements and aids to estimating are discussed and special emphasis is placed on the importance of scope definition. Different types of estimates are discussed and the influences on estimate accuracy are highlighted. The chapter concludes with the final review process of estimates.

Chapter 4 highlights the methodology of conceptual cost estimating in the engineering industry. The different types of conceptual cost estimating are mentioned with special emphasis on Ratio Conceptual Cost Estimating (RCE). Different ways of improving this form of cost estimating are discussed.

Chapter 5 reiterates the importance of a properly developed cost database. The requirements of such a database as well as the process of data collection are mentioned. The necessary data adjustments (data normalisation) are discussed, as well as the implementation of the normalised data. Lastly, the structure of the database is set out with descriptions of the main cost-bearing activities in a typical petrochemical development.

Chapter 6 portrays the effects of cost escalation and why it needs to be included in future project costs. It also covers risk management, the effects of proper risk management as well as the process or methodology of risk management. Inflation has a strong influence on cost escalation and is therefore discussed. Reasons as to why

inflation occurs and how to address it are mentioned. The use of cost indices, to apply escalation as well as the general management of escalation, are outlined. The reasons as to why it is necessary to include contingency in an estimate, misuse of the contingency, and management thereof are discussed

Chapter 7 elaborates on the impact of time on the construction schedule and how time can affect costs on the project. The financial forecasting process is set out in this chapter and is enhanced by cash flow analysis.

Chapter 8 discusses the practical application of Ratio Conceptual Cost Estimating (RCE) in the petrochemical industry, based on a developed database.

Chapter 9 provides the conclusion and recommendations of the study.

CHAPTER 2

COST CONTROL PHILOSOPHY

1.0 INTRODUCTION

When building a plant, cost control means regulating expenditures within the authorised budget while providing a plant of the desired quality within the time limit specified (Aoieong, Tang & Ahmed, 2002: 182). According to Agrawal (2007: 68), the plant should be capable of producing a quality product at the specified design capacity. Cost control cannot end with analysis and prediction of capital costs. The philosophy of cost control should be threaded through the plant's design and construction. Cheng and Li (2004: 793) state that costs should be controlled during the design, procurement and construction phases.

Economic progress depicts the construction of factories and plants and these must be constructed with cost control as a barometer of the plant's success (Reinschmidt & Trejo, 2006: 761). Pena-Mora and Park (2001: 445) point out that most heavy industries and petrochemical construction projects are now built by what is termed "fast track" methods. Design, procurement and construction are done with significant overlap, often appearing to happen simultaneously. Fast track methodology is necessary because of rapidly developing technology and expanding markets. As the design of certain portions of the plant gets agreed, procurement on long lead items can start (Reinschmidt & Trejo, 2006: 761). The speed of construction places even more emphasis on cost control throughout the construction phase.

Viljoen (2008: EVM.SO4.1) points out that to properly control the costs involved in building a process plant, as with any other construction project, several cost components should be managed in such a way that management will know timeously of any changes that may cause the project to steer away from the target, which will be to finish in time and within budget.

The purpose of this chapter is to investigate the theory of cost control and what influences costs on a project, what influences profit and how these influences can be managed to allow for an increased profit? Profit forecasting begins with individual forecasting of actual project cost performance relative to the allotted project budget and

ends with cumulative forecasts of corporate profit (Kumar, Nottestad & Macklin, 2007: 141).

According to Walsh, Sawhney and Brown (2005: 162), to understand the application of profit and how it should be applied one must understand the concepts of cost and how cost influences the success of the project. Total cost is determined by the cost of the resources that are expended to complete the activity or produce an asset. Resources utilised are categorised as material, labour, plant and indirect costs. Money and time are often considered to be resources, but they only implement and/or constrain the use of the physical resources (Postula, 2004: 1.1). Several types of cost have been identified and are discussed in this chapter.

The process by which costs are determined and arranged to be presented is referred to as pricing. Several tools exist whereby the pricing of a project can be evaluated to allow management to apply certain cost factors that will influence the total price of the project. Economic ratios and concepts guide the costing of the project and can be used to forecast the estimated final cost of the project (Roztocki & Needy, 1999: 20).

Ferreira and Rogerson (1999: 407) indicate that the main components of costing on a project are material, plant, labour and indirect costs. It is therefore necessary to spend some time on these aspects to identify the milieu in which they are priced and what influence they have on the outcome of the project. The use of different types of material, the handling thereof, and the way they are procured play a role in the costing of this component which forms the largest part of the total project cost (Gibson, Wang, Cho & Pappas, 2006: 37). With the worldwide focus on the “human factor”, the influence of labour cost on a project and the ultimate feasibility of the project, labour cannot be overlooked. With labour comes productivity (Berg & Hinze, 2005: 829). Increased levels of skills can lead to more cost-effective construction which will increase the profit margin.

The starting point of all the above-mentioned influences on cost is the initial design of the plant (Farkas & Uys, 2004b:). Several engineering factors influence the cost of a project. Globalisation, life-cycle costing, computer aided design, standardisation, etc. are but a few. Hamaker and Compomation (2005: 29) state that good engineering will lead to improved processes as well as improved methods of construction.

2.0 PROJECT COST CONTROL

2.1 Historical perspective: Projects of historical significance

Cost control is based on cost estimates of a certain scope of work executed according to a certain plan of action (Louw, 2002: 213). Proper cost control will highlight any changes in cost and will provide the managers of the project with the task of dealing with these changes. Throughout history, mankind has had a great deal of experience executing projects of all kinds, but has not always been successful in learning from old projects. To gain some perspective, some historical projects will have to be studied.

If one considers some well-known historical projects it is astonishing to find how well certain projects were planned and controlled even in those early days. The Eiffel Tower (which will be discussed later in this study) for example weighs 6300 t and was constructed over a period of little more than two years and in a time where modern construction equipment was not available. According to Van Niekerk (2008: personal interview), many contractors have difficulty in completing much smaller projects in the same time frame with modern equipment. It is therefore important for the student of cost control to be aware of what was achieved in the past so as to work towards real progress and not stagnate in the drive towards more cost-effective projects.

2.1.1 Ancient Rome

Morton (1966: 15) describes how Marcus Agrippa probably became the greatest fountaineer in history. Agrippa and his lifelong friend, Octavian, were both in their early thirties when they defeated Julius Caesar. They found Rome in a deplorable state. Agrippa and Octavian both started working on the re-instatement of the infrastructure. Their first act was to dismiss the contractors who had mismanaged Rome's water supply for centuries. Having cleared the sewers and repaired the aqueducts, Agrippa built a new aqueduct (Aqua Julia), and erected 500 fountains and 700 basins and pools for public use, and all this in one year of construction. According to Morton (1966: 16), Agrippa applied stern planning and control methods during this time.

At the time of the first Gothic sack of Rome in AD 410 the 11 aqueducts totaling 494 km of which approximately 85% were underground were feeding 1212 public fountains, 11 great imperial thermae, and 926 public baths. All traces of this triumph of hydraulic engineering vanished during the barbarian invasions.

2.1.2 St Paul's Cathedral, London

Anonymous, (2010a: np) indicated that in 1668 Wren was invited to submit designs for a new St Paul's Cathedral after the previous one was badly damaged in the Great Fire. He produced the first model, the Great Model, and the Warrant Design. Both were rejected by the church authorities so he decided not to submit any further new designs, but a Surveyor General to the King's Works told him to go ahead "as ordered by His Majesty", (Downes, 1990: 23). The foundation stone was laid on 21 June 1675 and work continued until 1708. The cost of the cathedral was 736 752 pounds sterling. Wren was paid 200 pounds sterling a year during the cathedral's construction. The dimensions are: length overall 152 m, height to the summit of the transepts 74 m, internal diameter of the dome 34 m. The project took 40 years to complete. Mathews and Atkins (1957: 67) point to evidence of cost control during this project even though the schedule was not of great concern.

2.1.3 The Palace at Versailles

Blunt (1980: 35) pointed out that the Palace at Versailles was built to house 1000 nobles and 4000 of their servants, and another 5000 servants in the palace annexes. By 1685, 36 000 workmen with 6000 horses were engaged on the palace site under the direction of Mansart, Le Brun and Le Nôtre. Such numbers may be grasped when it is realised that the installation of 1400 fountains necessitated the diversion of the river Bièvre and 16 000 hectares of land being drained, (Berger, 1985: 112). One hundred statues were commissioned by Le Brun for the gardens alone. Construction lasted 25 years which, considering the size of the scope and the time in which it was done, is notable, (Littell, 2001:78). Baillie (1967: 169) refers to the emphasis on planning during this project which is one of the most important ingredients of cost control.

2.1.4 The Eiffel Tower, Paris

Barthes (1979: 7) indicated that in 1885 a wrought iron bridge over the Truyère River, designed by Alexandre Gustave Eiffel, was opened. This bridge was the highest arched bridge in the world. It was 122 m high and 564 m long and was supported by five truss work piers and a great parabolic arch with a 165 m chord. The deflection of the loaded arch was 8 mm, exactly as Eiffel had predicted. The bridge took five years to build (Barr, 1992: 32).

The contract to engineer, design, fabricate and construct a 300 m tower with a wrought iron structural mass of 6 300 t standing on a base of 125 m x 125 m was awarded to Eiffel & Co. on 8 January 1887. Eiffel had two years and a few months to construct the tallest tower ever conceived. He received a subsidy of $300 000 in three installments, the final upon completion. Less than one fifth of the project cost was covered by the subsidy. Eiffel had to make up the remaining $1,3 million from franchise rights he obtained on all the restaurants, café's, etc. over the next 20 years – if the tower was a success. The previous projects mentioned here were all considered to be public sector projects, funded by the tax payers or the church. The Eiffel Tower, however, was a commercial venture which had to be well planned to succeed, (Barthes, 1979: 101).

The tower was one of the first examples of large scale industrialised construction. All calculations had to be accurate to 0,1 mm. Eiffel's greatest difficulty came from the tower's odd angles. The elements were not repetitive as was the case with many of his bridges. Every piece had to be designed separately, taking into account the variable inclination of columns and braces along every meter of the tower's height. Each of the 2,5 million rivet holes were drawn in on the shop drawings, (Lavedan, 1979: 28). The rest were placed on the site. Finished pieces of iron were delivered by horse drawn drays from Eiffel's shops in Levallois-Peret, about 5 km away. They produced 400 t of girders and trusses a month, which were hoisted into position by steam-powered cranes. It reigned as the world's tallest structure for more than 40 years, until New York's Chrysler Building opened in 1930.

2.1.5 The Sasol Two and Three Projects

According to Louw (2002: 11), managing the engineering, procurement and construction of the vast Sasol Two and Three Oil-From-Coal Projects which were built at Secunda in South Africa presented a once-in-a-lifetime challenge. Resources had to be mustered from all over the world and formidable engineering and logistical problems solved to get a large diversity of high-technological plant and equipment on site. The construction of the plants on adjacent sites in a remarkably short time and within a tight budget, using a construction labour force with a combined peak number of 26 000 persons, was a remarkable feat.

In December 1974 the Sasol Two Project was announced. The decision to build a large oil-from-coal project was precipitated mainly by the 1973 oil crisis, which made oil-from-coal a viable proposition. The overall Sasol Two Project was completed in five and a

half years, including four years construction. In June 1980 terms, the Sasol Two Project cost R2,8 billion, (Pienaar: 1990: 22).

At the time that the Sasol Two Project was built, it was amongst the largest grass roots projects ever undertaken in the world. The plant was designed to convert roughly 13 million tons of coal per annum into gasoline, diesel, liquefied petroleum gas, jet fuel and a large range of by-products. This meant that a plant had to be engineered, designed, procured, constructed and commissioned which would produce roughly about ten times more liquid fuel from coal than the existing plant in Sasolburg (which was based on the Fischer-Tropsch Process) was producing.

Although Sasol was committed to using only proven processes, the scaled-up size of some of the proposed plants and equipment was astounding. For example, an oxygen plant had to be built capable of producing 12 000 tons of pure oxygen per day for gasifying the coal and for methane reforming. For each of the six oxygen units, each rated at just more than 2000 tons of 98,5% pure oxygen per day, this would in turn entail designing air-compressor motor sets rated at 35MW each and oxygen compressor motor sets rated at 12MV each, necessitating a completely new electricity supply philosophy with 132kV underground cables and dedicated 132kV/11kV transformers at each of the large drive motors.

In February 1979, following the Iranian Revolution, the Sasol Three Project was announced, as a duplicate of the Sasol Two Project. Profiting from the completed engineering and from the experience gained on the Sasol Two Project, that was 60% completed by that time, the Sasol Three Project was completed in three and a half years including a construction period of three years. Table 2.1 provides some statistics of the Sasol Two Project.

Process units	32
Major mechanical plant equipment items	6 100
Valves	100 000
Pipes, valves and fittings	1 250 000 t
Pipe spools fabricated and installed	33 000
Earthworks	7.5 million m^3
Piles	30 000
Concrete	400 000 m^3

Reinforcing steel	23 000 t
Structural steel	30 000 t
Concrete hyperbolic process cooling towers (2)	Base 108m height 156m
Cooling water circulation	180 000 m^3/h
Power station smokestack, with four smoke stacks housed in a concrete windshield	250m tall
Construction man hours	130 million

Table 2.1: Some statistics from the Sasol Two Project
Source: Louw, 2002: 13

The Sasol Two Project was announced in December 1974 and the first profit was made in December 1980. The Sasol Three Project was announced in February 1979 and the first profit was made during the first six months of operation.

The above-mentioned projects all have some historical significance and are all great engineering marvels. In all of these projects, proper budgeting and planning took place, instigating the success of the projects and illustrating the importance of cost control. Wellington (1887: 33) made the following observation on project economics:

> *"It would be well if engineering were less thought of, and even defined, as the art of constructing. In a certain important sense it is rather the art of not constructing; or, to define it rudely but not inaptly, it is the art of doing that well with one dollar which any bungler can do with two after a fashion."*

Goldman (1920: 15) made the statement:

> *"It seems peculiar and is indeed very unfortunate that so many authors in their engineering books give no, or very little, consideration to costs, in spite of the fact that the primary duty of the engineer is to consider costs in order to obtain real economy – to get the most possible number of dollars and cents; to get the best financial efficiency."*

De Puyfontaine (1972: 55) commented that in an early observation on expert advice and project cost in 1812, Louis Michel Thibault, pioneer engineer, architect and land surveyor at the Cape (South Africa), wrote:

> *"The Burgher Raaden under the various Dutch Governments have always been entrusted with public works and, as in all countries, they have employed labourers instead of availing themselves of the services of architects. Faulty, ridiculous and doubly expensive work has resulted…"*

Proper cost control and planning on any construction project is therefore not a "nice to have", but a necessity. It is clear from previous discussions in this chapter how important these aspects are when considering some projects of historical significance. Engaging people with a sound knowledge of cost control on a project will therefore be the first step in ensuring a fair profit margin.

2.2 Introduction to project profit forecasting

Construction, like any other business, is profit driven. A construction company which consistently enters into contracts with the aim to not make a profit will not succeed. Although there might be special circumstances where acquiring a profit will not be the main objective of the business, it remains the main reason why people are in construction. Kraus' (2007a: EST.18.2) definition of what profit entails is probably the most well-balanced:

> "*Profit is the amount included in a contractor's price to compensate the contractor for undertaking the risks associated with the project and to provide a return on investment."*

The management of a company first admits that the company has a cost control problem when consecutive projects consistently experience cost overruns (Patterson, 2006: IT.05.1). Lewis and Spencer (2007: OWN.03.1) and Hughes (1991: 1) indicate that isolated cases of cost overruns usually are justified and normally do not cause changes in whatever project cost control philosophy the company may follow. Searching for the reasons why cost overruns occur might not be a simple task (Lucas, 2007: OWN.05.1). Harris and DiCiesare (2007: CDR.17.3) and Postula (2004: 1.1)

show that in most cases the problem of consistent cost overruns can only be addressed by procedural change.

Muscianesi (2003: 2), Lukas (2006: EST.03.1), Harbuck (2007: EST.16.1) and Musgrove (2007: EST.19.1) indicate that in the beginning of a project, cost is the first concern. The estimator needs costs to complete his estimate and to submit a competitive price into the market (Schottlander, 2007: EST.06.1; Shirley & Banks, 2007: EST.11.1). He is therefore selling his project price to his management (Postula, 2004: 1.1). In many cases, after this sale, costs drops to a much lower position on the project priority list. Other project commodities such as schedule (Aslaksen & Vigerust, 2007: RISK.02.1), safety (Tuffs, 2008: 13), constructability (Lam, Chan, Wong & Wong, 2007: 36), etc. then take precedence.

According to Scott (2006: New York Times, 16 June) and Hill (2006: 347), in a highly competitive bidding market and especially in an economic construction recession, project pricing is forced down by market conditions. This and the current tendency of larger employers in South Africa to award contracts on a “lump sum” basis, shifts the importance of cost from the employer to the contractor (Van Niekerk, 2008: personal communication). This makes it even more important to understand cost and why it is important to control costs on any project (Lucas, 2007: OWN.05.1; Patterson, 2006: IT.05.1).

Profit forecasting begins with individual forecasting of actual project cost performance relative to the allotted project budget and ends with cumulative forecasts of corporate profit (Kumar *et al*., 2007: 141). These forecasts involve two categories: projects in progress and potential projects. The focus of this study will be on projects in progress. Based on these profit forecasts management can plan financial distribution (Aslaksen & Vigerust, 2007: RISK.02.1), making financial forecasting one of the most important managerial functions in an organisation (Sanders, 2007: 18).

Profit forecasting (DiMonica, 2006: 10; Tague & Morrison, 2007: 12) begins at project level. Fayek, Revay, Rowan and Mousseau (2006: 16) state that the project manager, with the assistance of the rest of the project team, forecasts future project expenditure. Sanders (2007: 16) and Struts and Griffis (2005a: 621) agree with these findings. More information can be found in Chapters 4, 5 and 7 of this study on the methodology of forecasting. The historical project expenditures and predicted expenditures are compared (Kraus, 2007a: EST.18.1; Shirley & Banks, 2007: EST.11.2) to the project

budget, resulting in a predicted project cost overrun or under run. These predictions for each project are accumulated in the predicted or forecasted project cost overrun or under run (Harris & DiCiesare, 2007: CRD.17.2). More information can be found in Chapters 4, 5 and 7 of this study on the methodology of forecasting.

Webb (2003a: 111) states that the importance of financial forecasting cannot be overstressed. Stenzel and Stenzel (2003: 181) show that team members might think that they are only responsible for one figure in the total forecast and therefore ignore the importance of their contribution to the total forecast. Refer to Chapter 7. Kenley (2003: 4) and Stenzel and Stenzel (2003: 183) refer to another ill-conceived approach - that of being very conservative in the forecasts, thinking that this will lead to a cost under run, which will result in a saving which is better than overspending. Adopting these attitudes will lead to continuous inaccuracy and will only compound the forecasting problem (Eldenburg & Wolcott, 2005: 10).

2.3 Regaining control over project costs

Stenzel and Stenzel (2003: 2) define cost as follows:

> "*Cost is an outflow of a resource, whether in cash, as a payable, a rendered service, or a trade or barter that is consciously made with expectation of benefit to the organisation: goods, property, or service required."*

Cost control on the other hand is defined by Azhar, Ahmed and Caballero, (n.d.: 1) as follows:

> *"Cost control is a process to hold expenditures within budget by monitoring and appraisal of the cost performance."*

Understanding the definition of cost control is the first step towards establishing a proper cost control programme (Stenzel & Stenzel, 2003: 37-38). An effective programme consists of an integrated system of work flow which directs daily design and construction efforts (Kraus, 2007a: EST.18.1). These paths incorporate the efforts of all project functions, thereby providing the following control features:

- A system of checks and balances.

- Easy access to current project data.
- Easy comparison of project progress with current expenditures.
- Minimisation of cost overruns through early detection and redirection.

According to Azhar *et al.,* (n.d.: 1) and Establishing a Cost Control System (2008: online), a company project cost control programme is actually a work flow procedure in itself. This procedure can be as well-defined as possible but if it is not well communicated between the different departments or disciplines within the organisation, good cost control will not be realised (Al-Jibouri, 2003: 143). Figure 2.1 indicates the basic communications affecting cost control.

To ensure that project costs are important employee concerns, management should first initiate a company project cost control programme. This programme should include the contribution of each department or project function. The task of enforcing a project cost control programme lies with management (Ciccarelli, 2003: CDR.12.1). Such a project cost control programme is manifested in a work flow procedure rather than a list of historical budget and cost data. It should be a well-balanced system, not too simplified but also not over-controlled which might be very costly. Azhar *et al.,* (n.d.: 1) illustrate in Figure 2.2 how such a system can function.

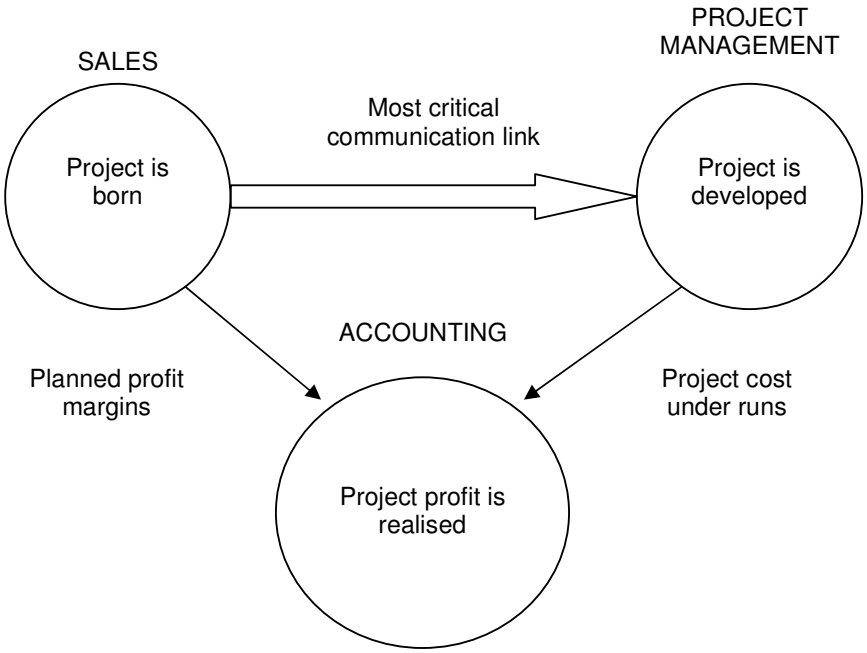

Figure 2.1: Basic corporate communications affecting cost control

Source: Tompkins, 1985: 7

Figure 2.2 describes the basic framework to develop an integrated cost estimation and control system. The methodology for developing such a system begins with a requirement analysis. Azhar *et al.,* (n.d.: 2-3) state that requirements are broken down into a coding system, cost estimation and control processes, and input and output formats.

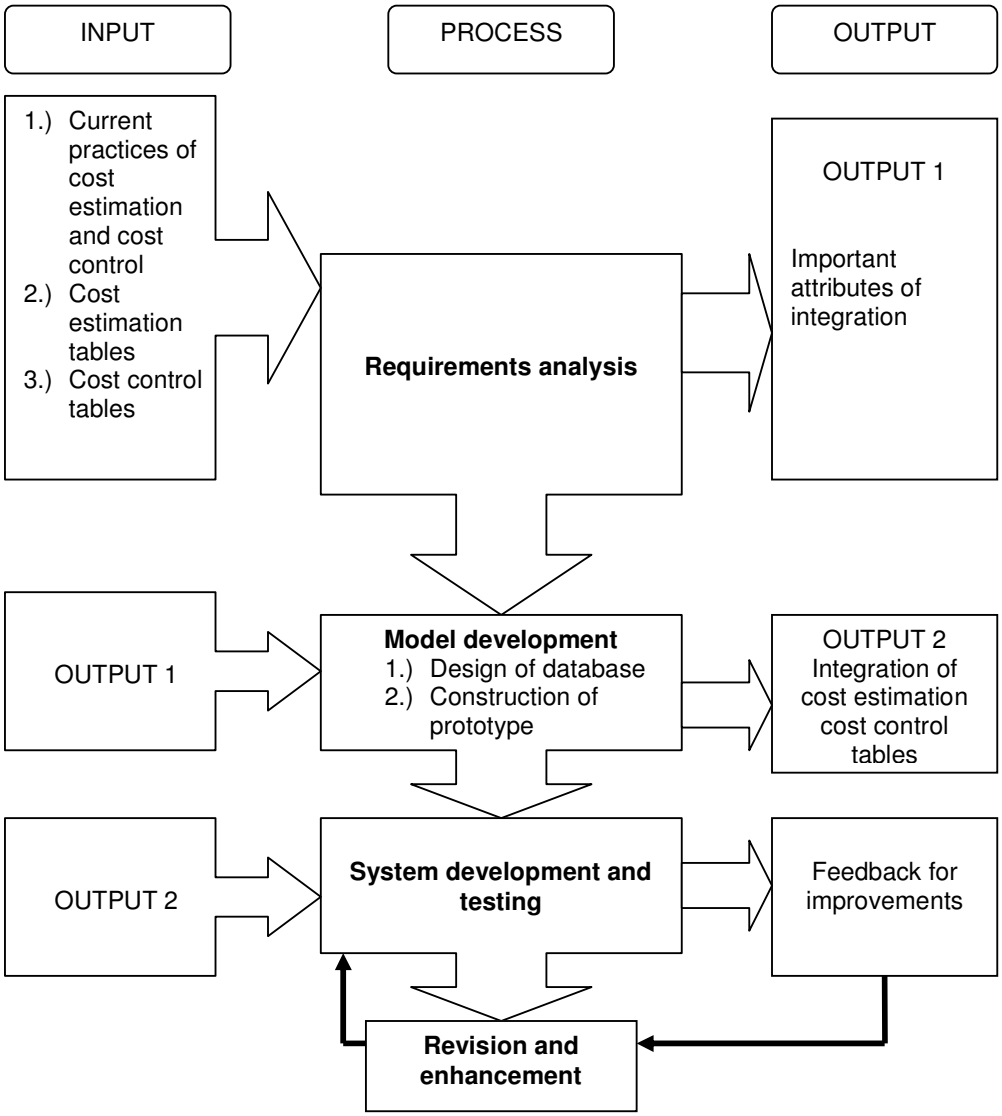

Figure 2.2: Basic framework to develop an integrated cost estimation and control system

Source: Azhar *et al.,* n.d.: 5)

Once the requirements have been analysed a model can be developed. Azhar *et al.,* (n.d.: 3) stress the importance of automatic transfer of estimation data to the control part. Keeping this in mind the first step of model development can be taken, which is

establishing data flow diagrams. Based on the data flow diagrams a cost control model can be developed.

3.0 CONCEPTS OF COST

Cost is the value of an activity or an asset (Azhar, *et al,* n.d.: 1). Stenzel and Stenzel (2003: 2) also refer to cost. Their findings are structured earlier in this chapter. Generally this value is determined by the cost of the resources that are expended to complete the activity or produce the asset. Resources utilised are categorised as material, labour, plant and indirect costs. Money and time are often considered to be resources but they only implement and/or constrain the use of the physical resources (Postula, 2004: 1.1).

The final activity or asset produced depends on the budget and the time allocated to the project (Slight-Gibney, Grenci & Blackwell, 2004: 287). Gardiner and Stewart (2000: 251) indicate the importance of time in construction. They further state that by studying the plethora of evidence in final reporting on completed projects, it can be seen that conservatively speaking almost 50% of all projects show cost overruns. Gardiner and Stewart (2000: 252) further allude to the role of Net Present Value (NPV) and how this tool can assist in acknowledging the importance of time and budget in a construction project. Further detail on NPV can be found later in this chapter. Dunlap (1991: New York Times, 8 April) indicates the effect of timing in construction when considering economic cycles.

The material content (Dobler, Burt & Lee, 1990: 242) of an asset is not just the physical composition of the asset. Thomas, Riley and Messner (2005: 808) agree with these findings. The value of the asset might also include for items such as scrap material (waste), manufacturing parts, consumables (such as formwork), expendable safety equipment and transport (Ashworth, 1992: 8; Wainwright & Wood, 1991: 18). The labour content of a price is not only the direct labour utilised to complete a certain task, but it also includes the engineer's design, the foreman supervising the work, etc.. (Brock & Palmer, 1986: 106). The indirect cost refers to the resources needed to support the specific activity (Brock & Palmer, 1986: 123). This includes all indirect costs such as head office overheads, management, etc. (Eldenburg & Wolcott, 2005: 39). A final aspect of the costing structure is the profit that management adds on top of the total of the direct and indirect costs (Harris & DiCiesare, 2007: CDR.17.1; Paek, 2000: 40). Profit is determined by market conditions.

Further it is important to structure the cost elements within the material, labour, plant and indirect resources to understand how they influence the total cost of the activity. Eldenburg and Wolcott (2005: 38) indicate that this will also lead to a better understanding of how these costs can be controlled. This structuring directs the cost elements into four main structures: direct costs, indirect costs (Norfleet, 2007: EST.12.1), fixed costs, and/or variable costs (Eldenburg & Wolcott, 2005: 38-39; Stenzel & Stenzel, 2003: 74). In practice some costs may fall into more than one category.

3.1 Direct cost

Norfleet (2007: EST.12.1) defines direct cost as any cost that can be identified specifically with a final cost objective, such as a contract, project or job. In construction, direct costs do not represent all costs that can be identified specifically to a job. Generally, direct costs are limited only to the actual costs of construction craft, labour, material, equipment and sub-contracts. These costs are often referred to as “hard costs” and are integral to the installed or constructed component.

Eldenburg and Wolcott (2005: 38) and Norfleet (2007: EST.12.1) further describe direct costs as resources that are expended solely to complete an activity. Direct cost is any cost that is specifically identified with a particular final cost objective, but not necessarily limited to items that are incorporated in the end product as material or labour. These costs therefore include all direct labour and material costs to complete a specific activity. Factors such as poor productivity (Boyle, 2007: CDR.02.1 and Whiteside, 2006: EST.08.1) will be reflected in the labour cost as an indirect factor. Waste on material, for instance, will be included in this cost but any recoverable portion must be deducted since this will save on the total project cost.

3.2 Indirect cost

Indirect costs are those resources that need to be expended to support the activity, but which are also associated with other activities (Eldenburg & Wolcott, 2005: 38). In other words, it is any cost that is not directly associated with a single final objective, but with more than one objective. Norfleet (2007: EST.12.1), however, indicates that there must be a relational requirement between indirect cost and the function base it supports. There must be a distinct relationship between the two in order to constitute an appropriate allocation of the indirect cost. Norfleet illustrates his statement by means of

this example: there is an unquestionable relationship between a base wage rate and social security taxes. As the base rate increases, so does the tax attributed to that rate. Indirect costs are allocated to an activity based upon some direct cost element. An indirect rate is calculated based upon the casual and beneficial relationship between the indirect cost, or group of costs, being allocated and the base to which the rate will be applied.

Indirect costs can also be described as “overhead costs” or “burden costs”. These costs include, amongst others, items such as administrative costs, providing and maintaining equipment, expenses for utilities, taxes, etc.

3.2.1 Overhead cost

This form of cost is believed by various authors (Enshassi, Aziz & Karriri, 2008: 36 and Ibbs & Nguyen, 2008: 30) to be a form of indirect cost and by some (Norfleet, 2007: EST.12.2) to be synonymous with indirect cost in its broadest sense in that it cannot be assigned to a specific contract without some method of allocation. Any group of homogeneous costs can be combined into a specifically designated overhead category and allocated across various contracts using some established methodology. Norfleet (2007: EST.12.2) stated some of the more common overhead categories:

- Labour overhead – This represents the cost associated with payroll expenses other than a person’s base wage rate. Labour overheads can also include the labour cost of employees supporting multiple contracts whose time must be allocated in some fashion. Certain other costs such as training can also be allocated to this group.
- Specialised labour overheads – The most common form of specialised labour overheads can be found in engineering, manufacturing and material handling.
- Fringe benefits – A component of labour overheads addressing only the payroll expenses that are levied upon or otherwise associated to employee wages are fringe benefits. Examples of these include payroll taxes, unemployment taxes, health insurance, etc.
- Field office overheads – In construction, field office overheads consist of the indirect costs that are located at and assigned to a particular project but are not part of the installed or constructed project.

- Home office overheads – Home office overhead, in construction, is the indirect cost assigned to the home office and associated with the overall cost of doing business.

3.2.2 Burden cost

Cascio (1982: 99) indicates that “burden” is the term loosely used to describe the application of some form of indirect cost such as an overhead to a direct cost such as labour. This form of cost is most often used to indicate the allocation of labour overhead to a base wage rate and does not mean inclusion of all indirect costs. That is, unless the term is further described as a “fully burdened labour rate”. In that case it is assumed that all allocable indirect costs have been included and the only question remaining is whether profit or fee has been applied. A “fully burdened labour rate” is also referred to as a “wrap rate”.

3.3 Fixed cost

Eldenburg and Wolcott (2005: 41) refer to fixed cost as cost that must be provided for irrespective of what the volume of work is. Fixed costs are therefore not influenced by small changes in factors such as productivity, sales and services provided. These costs can be direct or indirect costs. Tools or equipment to perform a certain task is, for example, a fixed cost. If these tools are used on more than one activity it will be an indirect fixed cost.

3.4 Variable cost

As opposed to fixed cost, variable cost is based upon volumes and can also either be a direct or indirect cost. Utilities used to perform certain tasks can, for example, be an indirect variable cost. According to Eldenburg and Wolcott, (2005: 41), variable cost changes proportionately with changes in activity levels.

4.0 COST ACCOUNTING AND COST MANAGEMENT

Cost accounting is the historical reporting of disbursements, costs and expenditure on a project (Humphreys, 1984: 40). Historical data can provide a sound basis of forecasting and budgeting for future projects. Refer to Chapter 5 for more information on historical cost data and the use thereof.

Accounting systems focus and assign control responsibilities for some combination of profitability, revenue, investment or cost activities. In other words, accounting systems identify individuals or segments called responsibility centres (Stenzel & Stenzel, 2003: 60). Therefore, organisations that hold the responsibility centres accountable for safeguarding assets and contributing to profitability, by definition, employ an accounting system structure called responsibility accounting.

Any accounting system should include three basic steps: recording, classifying and summarising cost data. Each business should have its own approach to classifying and summarising costs (Stenzel & Stenzel, 2003: 2). This methodology is called the "code of accounts". Another approach to classifying costs is the use of a Work Breakdown Structure (WBS) (Zhao, 2006: RISK.05.1). Not only does a WBS provide a framework for planning and controlling the resources needed to perform the technical objectives, it also facilitates a summary of project data regarding the cost and schedule performance (Zou & Lee, 2006: CSC.13.1).

Regardless of how cost elements are classified and grouped, it is important that this is done in a manner that is consistent with the way in which future work is estimated and budgeted (Humphreys, 1984: 40). Historical cost records represent the way a company is conducting its business. These documents can be analysed to determine whether improvements have been made and how costs may trend in future.

The net effect of cost management is increased profit (Stenzel & Stenzel, 2003: 2). Profitability, variously interpreted as net income, equity value and return on investment is a results-focused indicator watched more carefully than any other performance measurement category. At the core, profit only has two components – revenue and cost. Stenzel and Stenzel (2003: 3) describe cost management as follows:

> *"Cost management is the use of cost accounting systems and methods to guide current and future operations toward specified objectives; the analysis and interpretation of cost data is critical to the decision-making process."*

Cost elements and cost structure can be displayed in various ways to management (Eldenburg & Wolcott, 2005: 6). Chapter 7 can be consulted for the development of a cost forecasting model for presentation to management. Lewis and Spencer (2007: OWN.03.1) and Lucas (2007: OWN.05.1) describe four basic methods on how cost

information is applied to cost management. These are cost estimating, cost trending, cost forecasting and life-cycle costing. The methodology of these methods will be discussed in more detail in the following chapters, but a basic description of each method in this chapter will add to the overall understanding of cost control philosophy.

4.1 Cost estimating

According to Clark and Lorenzoni (1985: 5), the prediction of quantities and costs involved to complete an activity are referred to as estimating, Clark and Lorenzoni (1985: 5) also state that the estimate should contain a step-by-step plan as to how the project team feel or predict the project will be executed. In case of the design, a flow diagram and equipment list should be produced. These documents predict the final design after engineering. The estimator makes use of this information and translates it into a monetary value by applying unit costs to the quantities (Chuong, 2007: EST.07.1). In doing this the estimator is forecasting the final cost to procure the material and to install it on site (Lukas, 2006: EST.03.1). The timing of the purchase should also be predicted to allow for the necessary escalation. Refer to Chapter 6 for more information on escalation. Planning (Harbuck, 2007: EST.16.1) and scheduling (Hollmann, 2007b:8; Stratton, 2007: EVM.04.1) therefore become important costing factors as well. The most important considerations when performing an estimate are:

- A well-defined scope.
- A cost element structure.
- Historical cost data.

The methodology of estimating varies depending on what the purpose of the estimate is (Clark & Lorenzoni, 1985: 5). More detail on estimating can be found in Chapters 3 and 4.

4.2 Cost trending

Cost trends are established from historical cost data (Clark & Lorenzoni, 1985: 268). Tompkins (1985: 20) describes trending as follows:

> *"Trending is a project cost and schedule control technique used continuously through all stages of a project to illustrate deviations from the control budget or project schedule."*

Tompkins (1985: 20) reports that trending offers management the opportunity to make project decisions in advance of commitments. Management questions might focus on how expenditures are trending relative to the physical progress or accomplishments. Cost trending can be a helpful tool for management to make certain decisions regarding the management of the project (Bent, 1982: 125).

4.3 Cost forecasting

The main focus of this study is the improvement of the financial forecasting methodology. Tompkins (1985: 18) describes forecasts as predictions of the cost at completion for the cost elements in progress. Kenley (2003: 37) comments as follows on the importance of financial forecasting:

> *"The success of a company depends on the ability of the management to foresee and to prepare for the future. A contractor can use cash flow forecast techniques to improve his financial position and remove the financial risk which threatens so many construction companies."*

Kenley (2003: 37) describes the importance of why it is necessary to do cash flow forecasts. It is important to look at the complete cost spectrum and to include direct and indirect costs. Kenley (2003: 37) states that the most important reasons for forecasting are firstly, the availability of funds and secondly, the possibility of loss in interest. Ashworth (2004: 352) extends the reasons for forecasting and adds cost estimating, final account predictions and whole-life costing to the list. Ashworth (2004: 403) also states that although financial forecasting is important one should also be aware of future changes to technology, policy-making, labour, etc. All of these factors will have an influence on the future cost of a project.

The purpose of the forecast will be to determine the expenditure to date by making use of project cost data and adding to this the estimated cost to complete the remaining portion of work or scope not completed (Clark & Lorenzoni, 1985: 196). It is in this latter part of forecasting (estimating the value of the portion to complete) where the focus of the study lies.

4.4 Life-cycle costing

Zhang, Novick, Hadavi & Krizek (2008: 25) indicated that designed life of a structure ultimately has an effect on the cost of such a structure. Flanagan and Norman (1983: 2) and Sterner (2000: 387) indicate that life-cycle costing is associated with an asset and extends the cost management information beyond the acquisition of the asset to the use and disposal of the asset. Asset acquisition consists of the design phase and the construction phase. Generally, cost elements are segregated into these phases because design costs are often recovered over more than one asset (Sterner, 2000: 387; Life Cycle Costing, 2008a). The design and development of a new aeroplane is amortised over the production. The design of a housing project is recovered through sales of the houses built (Life cycle cost analysis, 2008c: online).

A life-cycle approach, that is an approach that takes explicit account of the life-cycle costs of assets, is essential to decision-making in four main ways (Flanagan, Kendell, Norman & Robinson, 2001: 53; Flanagan & Norman, 1983: 2):

- It identifies the total cost commitment undertaken in the acquisition of any asset, rather than merely concentrating on the initial capital costs (Lewis & Spencer, 2007: OWN.03.4).
- It facilitates an effective choice between alternative methods of achieving a stated objective. For example, choosing between two machines to perform a particular production process. It takes full account of the probability that the various options are likely to exhibit somewhat different patterns of capital and running costs, and provides a set of techniques for expressing those costs in consistent and comparable terms.
- A life-cycle approach is a management tool that details the current operating costs such as machinery, individual construction elements or complete construction systems.
- Life-cycle costing also identifies those areas in which operating costs might be reduced, either by a change in operating procedures or changing the relevant system.

Life-cycle costing techniques can be applied in any area of economic decision-making (Mearig, Coffee & Morgan, 1999: 2); but they are particularly relevant to the proper identification and evaluation of the costs of durable assets. As a result they are especially relevant in the construction industry (Flanagan & Norman, 1983: 2). Whether

complete structures or individual elements are considered, a decision is being made to acquire assets that are intended to last and to be used for a number of years (Flanagan & Jewell, 2005: 1; King, 2008: online). These assets will commit the owner not only to initial costs, but also to subsequent running costs, and also to periodic repair and replacement costs. Equally important, decisions made at the initial design stage invariably effect future running costs and the economic use of the structure or plant. More recent sources refer to whole-life appraisal (Flanagan & Jewell, 2005: 2; Life Cycle Costing, 2008b: online).

5.0 PRICING

Pricing can be described as the process by which the cost of a project is established. It refers to a set of tools and techniques which can be used in the costing process. Some of these tools would include pricing strategies, sales and revenues, return on investment, return on sales and break-even analysis.

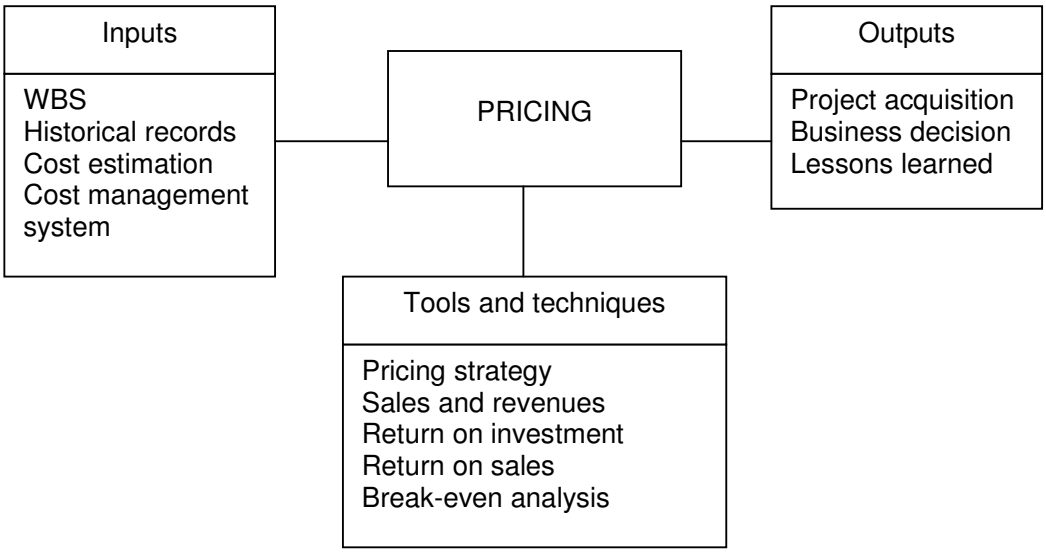

Figure 2.3: Analysis of the pricing process

Source: Singh, 2004: 2. 2

The process of pricing is illustrated in Figure 2.3. The inputs will be the documents which will include items such as WBS (work breakdown structure) (Pickett & Elliott, 2007: EST02.1), historical records (Melamed, Skokan, Zenkowich & Kocher, 2007: RISK.06.1), cost estimation and cost management system. The tools and techniques are the mechanisms applied to the inputs to produce the outputs and include pricing

strategies, sales and revenues, return on investment (ROI), return on sales (ROS) and break-even analysis (Webb, 2003a:36; Peters, Timmerhaus & West, 2003: 328).

Xu and Tiong (2001: 77) point out that normally the pricing strategy in construction will involve the cost plus mode where all direct and indirect costs are calculated and a fee or profit is added to this value. This can in a way be seen as the traditional pricing strategy. Xu and Tiong (2001: 77) mention front-end loading and back-end loading as earlier forms of cash-flow manipulation. In these strategies the price of work that is expected to happen earlier or later in the contract are raised or lowered and thus influence the cash-flow (Chen, 2007: PM.02.1). Claim loading can also occur when specific items have been identified as items that will form part of extras to the contract. The unit rates for the items are then increased with a net result of a higher total price for the same additional scope.

5.1 Pricing scenarios

Essentially there are two scenarios in pricing strategy which frequently occur (Van Niekerk, 2008: personal communication). Both Type I and Type II are specific situations but with different business objectives. Type I situation is to price the work in such a way that should the firm win the tender, it will be able to conduct the work in such a way that a reasonable profit is retained. Type II pricing procedure is similar to Type I but with the variable or irregular market conditions. The firm might be desperate for work to retain its valuable resources or it might try to enter a new market.

5.2 Economic ratios and tools

The expenditure for a business is normally easier to predict than the earnings. Some economic ratios exist to assist management in predicting the earnings of the business. As previously mentioned, they are ROI, ROS and break-even analysis. Some inputs or resources are necessary to make the business successful:

- Natural resources: The material used to manufacture a product as well as the buildings and structures to assist in the production process can be referred to as natural resources.
- Capital: The assets through which business are done or the cash that makes it happen is known as capital (Peters *et al*., 2003: 268).

- People: By many considered to be the most important asset of a business. The abilities of the people employed by the firm are vital to the success of the business.

These inputs or resources provide the background to the economic ratios. All ratios must be taken in context and should be reviewed on a monthly basis to identify trends. The following ratios are commonly used.

5.2.1 Return on investment (ROI)

Return on investment is one of several approaches to building a financial business case (Webb, 2003a: 36). Management evaluates the investment potential by comparing the magnitude and timing of expected gains to the investment costs. This approach can be used to make "go/no-go" decisions on asset requirements or the implementation of programmes.

Basically two types of return-on-investment calculations exist. Simple and complex return on investment calculations can be described as follows:

Simple ROI

$$\text{ROI} = \frac{\text{(gains - investment)}}{\text{investment cost}}$$

Simple ROI works well in situations where both the gains and the costs of the investment are easily known and where they clearly result from the action (Peters *et al.*, 2003: 328). The higher the ratio as calculated by the formula, the better the investment. The ratio in itself does not, however, give any indication of the scale of the investment or the magnitude of the returns or risks in the investment.

Complex ROI (Dupont method) (Humphreys, 1991: 106).

$$\text{ROI} = \frac{\text{average yearly profit during earning life}}{\text{(original fixed investment + working capital) expressed as a percentage}}$$

Other financial ratios are sometimes treated as ROI figures and include ratios such as return on capital, return on total assets, return on equity and return on net worth. All of these ratios have the single goal of expressing cumulative cash flow results of an investment over time (Humphreys, 1991: 106-109).

5.2.2 Return on sales (ROS)

Return on sales gives one an idea of the after tax profit to sales (Newnan, Eschenbach & Lavelle, 2004: 212). If a business is experiencing poor cash flow it could be because the markup or profit allowed is not enough to cover expenses. The return on sales (ROS) ratio can assist in pointing this out and allow management to adjust the profit margin. Should this figure drop over time it might give an indication that the firm might soon run into financial difficulties.

$$ROS = \frac{\text{net profit}}{\text{sales}}$$

5.2.3 Break-even analysis

Break-even analysis involves finding the level of sales necessary to operate a business on a break-even basis (Webb, 2003a: 36). Total costs will equal total revenue. In other words, profit will be nil (Paek, 2000: 40). The following are typical terms used in performing a break-even analysis (Paek, 2000: 40):

- Selling price (SP): This is the price that each unit will be selling for and is expressed as cost per unit.
- Variable costs (VC): These are costs that vary in proportion to sales levels. It can include direct material and labour (Eldenburg & Wolcott, 2005: 41), the variable part of manufacturing overheads and transportation. VC is usually expressed as a cost per unit (Paek, 2000: 40).
- Contribution margin (CM): The difference between the selling price and the variable cost is referred to as the contribution margin.
- Fixed costs (FC): These costs remain fixed irrespective of the number of sales (Eldenburg & Wolcott, 2005: 41). These are generally costs such as overhead administrative costs, cost of interest and depreciation, etc. The fixed costs are generally expressed as a lump sum.

- Units (X): Units refer to the number of items produced or sold. For the purpose of break-even analysis the number of items produced is considered to be equal to the number of items sold during the same period.

Paek (2000: 40) states that each project is like a custom item that is built to serve a special need, so that there are many decisions to be made before deciding whether to bid. Examples can be, for instance, what labour force will be available for the project, or whether the company will be able to keep up with their current workload should they acquire the new project.

Break-even points are not rigid or static. They change with every decision made by management. The break-even volume changes when the margins are raised or lowered and when the efficiency of the operation rises or falls. It changes when there is purchasing or selling of equipment and it changes every time there is an alteration in the overhead spending. It can be considered that the break-even point is only of academic interest and that companies are interested in the profit path (Nottestad & Macklin, 2007: 142-143) above the break-even point and how it is affected by those factors that are controllable. Figure 2.4 indicates a typical break-even point with “cost” at the lower end of the graph and “revenue” at the top end.

The formula for break-even analysis can be noted as follows:

$$SP(X) = VC(X) + FC$$

or

$$X = FC / (SP – VC)$$

Since much data gathered in solving a problem represent projections of future consequences, there may be considerable uncertainty regarding the data’s accuracy (Newnan *et al*., 2004: 285). Since the desired result of the analysis is decision-making, an appropriate question to ask would be: To what extent do variations in the data affect my decision? When small variations in a particular estimate would change selection of the alternative, the decision is said to be sensitive to the estimate. To better evaluate the impact of any particular estimate, the variation to a particular estimate that would be necessary to change a particular decision, is computed. This is referred to as sensitivity analysis (Flanagan *et al*., 2001: 57; Newnan *et al*., 2004: 285).

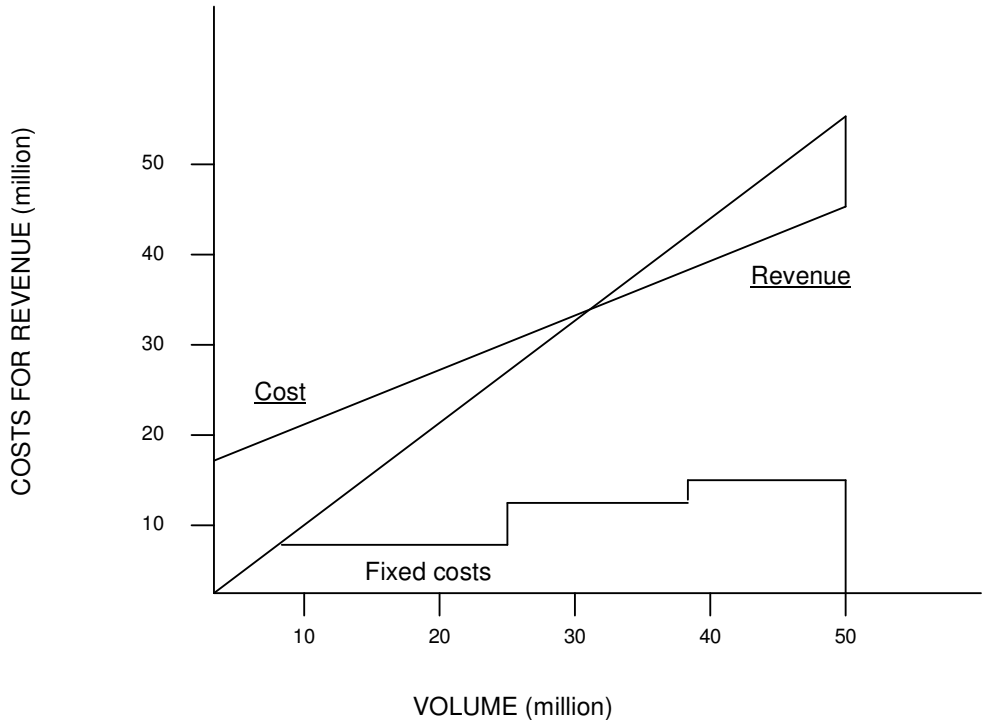

Figure 2.4: Typical break-even distribution
Source: Paek, 2000: 41

5.2.4 Earned value

Prentice (2004: 2) describes earned value as follows:

> *"The periodic, consistent measurement of work performed in terms of the budget planned for that work. In criteria terminology, earned value is the budgeted cost of work performed. It is compared to the budgeted cost of work scheduled (planned) to obtain schedule performance, and it is compared to the actual cost of work performed to obtain cost performance."*

The concept of earned value has been around for more than 40 years. Webb (2003b: 3) indicates that it has been used on some projects with great success, but it has not been used extensively throughout all projects. The main reasons why earned value was not used is that it was too complicated and too costly. These reasons, amongst others, prevented extensive use of earned value outside the USA for the first 30 years (Stratton, 2007: EVM.04.1).

Earned value is a basic concept that goes back to industrial engineering and accounting procedures well before project management was a recognised discipline on projects (Webb, 2003b: 3). Prior to the introduction of earned value techniques, managers were relying on Gantt charts and Critical Path Analysis for scheduling aspects. The difference between planned costs and actual expenditure was reported to get an indication of the financial progress on the project. Organisations were embarrassed by high cost overruns on some projects. These overruns could not have been predicted until it was too late. Studies and investigations brought forward a fairly simple concept (Owen, 2007: EVM.01.1). According to Kuehn (2007: EVM.05.1), a detailed plan and a detailed valuation should be made of the scope of work before the project is started. Notes should be made against each reporting point of the following:

- How much value should have been achieved according to the plan?
- How much value has been created according to the work done?
- How much money has actually been spent?

These three values are illustrated in Figure 2.5. Webb (2003b: 18-24) defines some earned value terminology by means of an example. Refer to Figure 2.6 for more detail. Webb describes a project with an estimated cost of £80m, with a four year duration. After two years the cumulative cost is planned to be £40m. The actual status after two years derived from project accounts accumulates to £30m. Does this mean that the project is actually doing well having spent less than planned after two years or does it mean that the project is behind schedule?

To establish the situation an assessment needs to be made as to what actually has been accomplished after two years. If the updated programme indicates a 56% completion status, which is represented by the bracket in Figure 2.6, it will mean that the project has a current earned value of £45m against an actual spend of £30m.

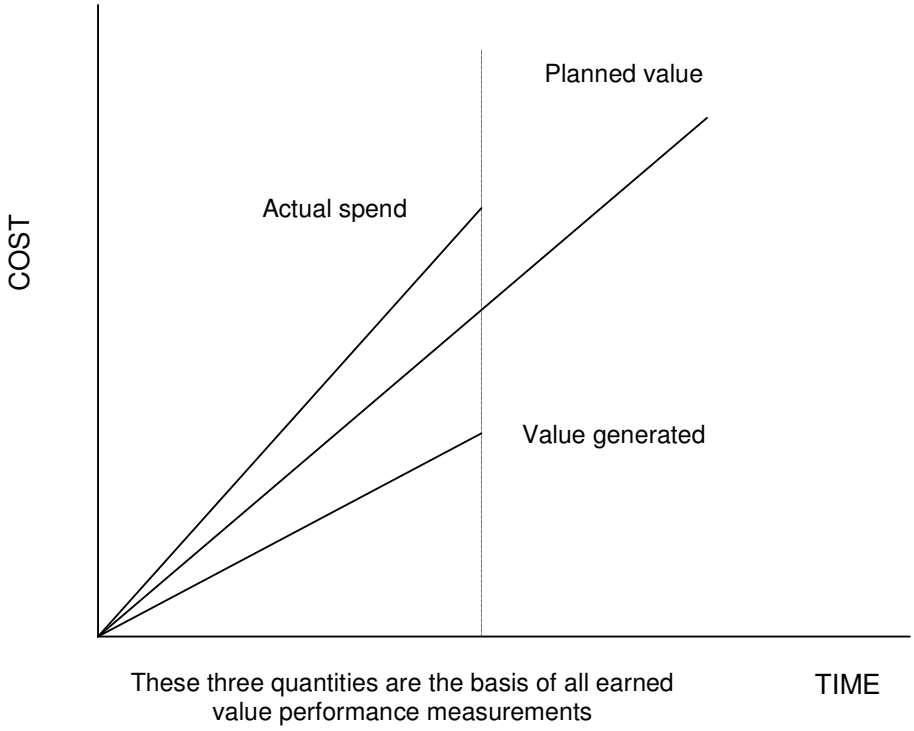

Figure 2.5: Adding the value generated as time passes gives a greater insight into the project than simply the planned actual values

Source: Webb, 2003b: 2

Webb (2003b: 22-24) explains a few common terms frequently used in earned value analysis:

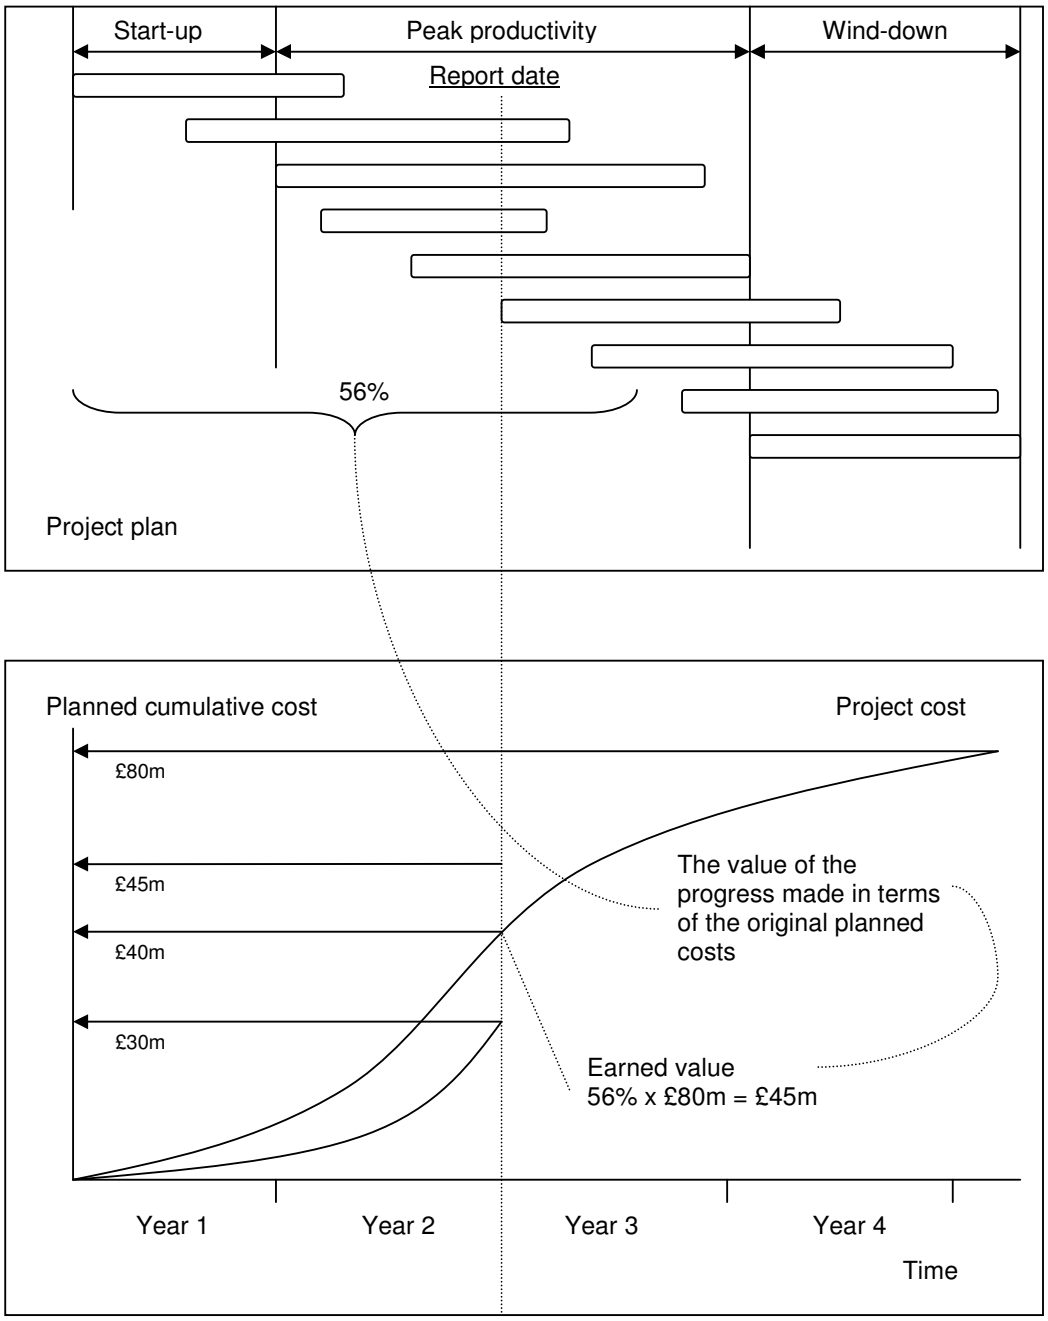
- Budgeted cost for work scheduled (BCWS): – This is the sum of all the planned costs in the project, or any given part of the project, up to the reporting date (refer to the £40m sum in Figure 2.6).
- Budgeted cost for work performed (BCWP): This is the cost of all the progress achieved on the project, up to the reporting date. In the example it refers to the £45m value.
- Actual cost of work performed (ACWP): The total of all expenditure on the project up to the reporting date. This refers to the £30m value in the example.
- Cost variance (CV) = BCWP – ACWP: The numerical difference between the earned value and the actual cost at the reporting date.

- Schedule variance (SV) = BCWP – BCWS: The numerical difference between the earned value and the planned expenditure at the reporting point.

If the CV or SV is positive, the project is doing better than planned. Figures 2.7 and 2.8 indicate a cost and schedule variance using an earned value of £25m, which is different than that of the example, but now it depicts a negative situation instead of a positive situation. Determination of schedule slippage can be noted in Figure 2.8.

5.2.4.1 Earned value calculations

Webb (2003b: 24-25) describes two useful indexes in basic earned value calculations. They are:



Cost Performance Index: (CPI) (Cost efficiency) – The ratio of the value created to the amount spent at a point in time on the project.

$$CPI = \frac{BCWP}{ACWP}$$

Schedule Performance Index (SPI) (Schedule efficiency) – The ratio of the earned value created to the amount of value planned to be created at a point in time on the project.

$$SPI = \frac{BCWP}{BCWS}$$

Index values greater than one indicate performance either in cost or schedule terms that is better than planned. The CPI is perhaps the more useful of the two. It shows the real worth that is being created by the project. A CPI value of 0,85 indicates that for every monetary unit spent on the project, only 85% of that is being created on the basis of the original budget.

Adding the earned value to the cost curves at the project mid-point

Figure 2.6: Earned value assessment for a project that is running ahead of schedule

Source: Webb, 2003: 23

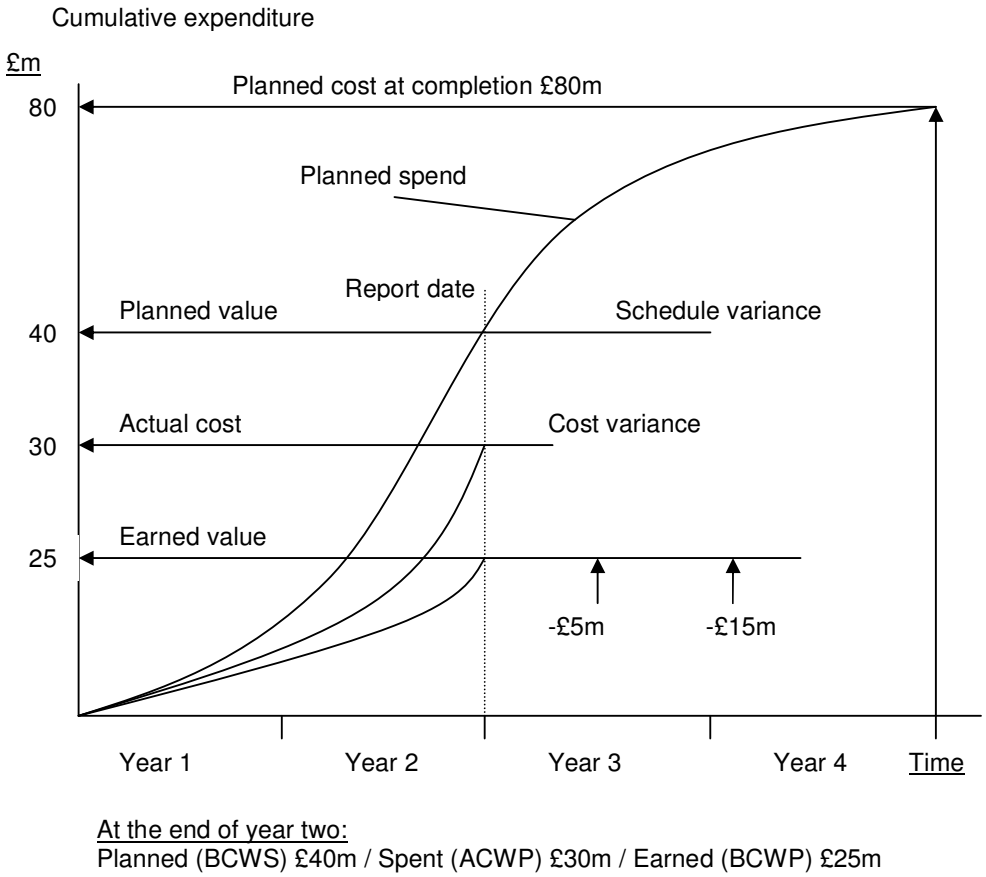


Figure 2.7: Cost and schedule variances

Source: Webb, 2003: 24

Webb (2003b: 25) states that history has proven that once a trend has been established, it tends to remain in force until the end of the project. If it does change, it normally changes for the worse. Two formulae can be derived for estimating both the expected cost at completion and the expected completion date on the assumption that the trends seen up to the reporting point continue until the end of the project.

Estimated Cost at Completion (EAC) – The estimated final cost of the project, calculated as follows:

$$EAC = ACWP + \frac{BAC - BCWP}{CPI}$$

Where: BAC is the Budgeted Cost at Completion.

Historical data indicates that in the USA the EAC forecasting method tends to be optimistic. It depends on the same level of cost efficiency to continue to project completion, but this rarely happens. For the overall duration of the project the formula also consists of two parts - the time elapsed up to the reporting date plus the estimated additional time to complete the project assuming the trends seen to date continue.

$$ETTC = ATE + \frac{OD - (ATE \times SPI)}{SPI}$$

Where: BAC is the Budgeted Cost at Completion.

ATE is the Actual Time Expended

OD is the Original Duration

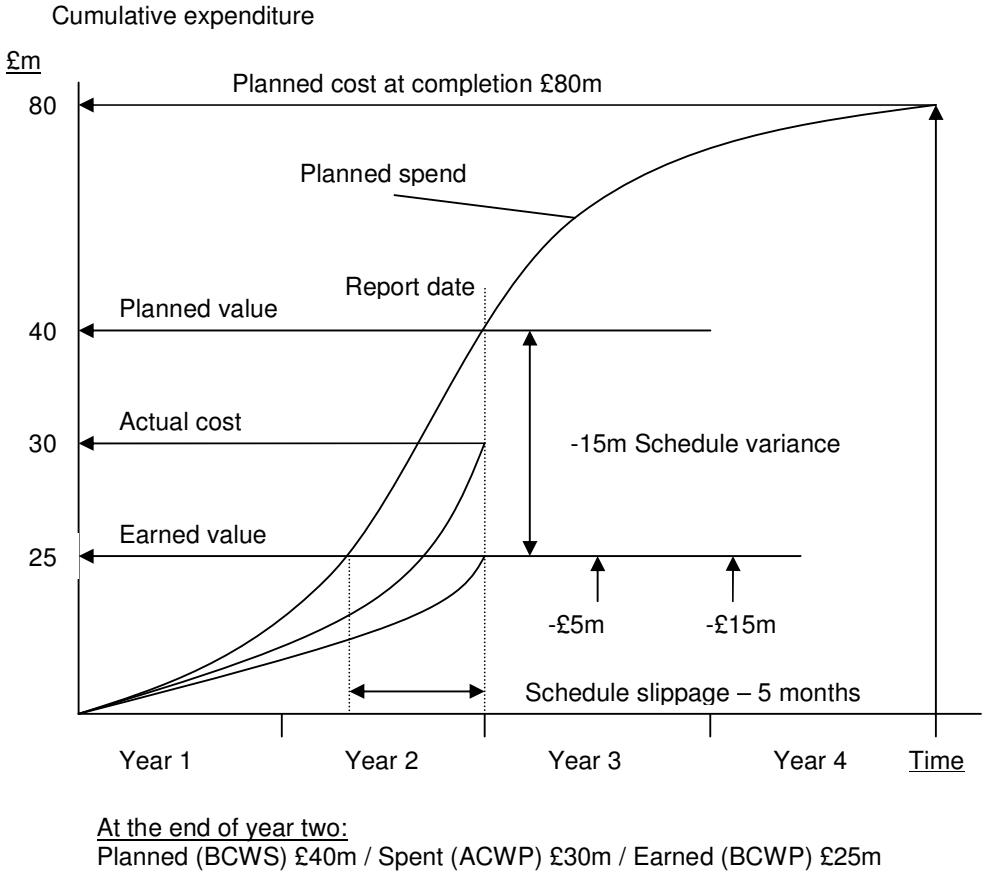

Figure 2.8: Schedule slippage can be established from the earned value and the planned S-curve

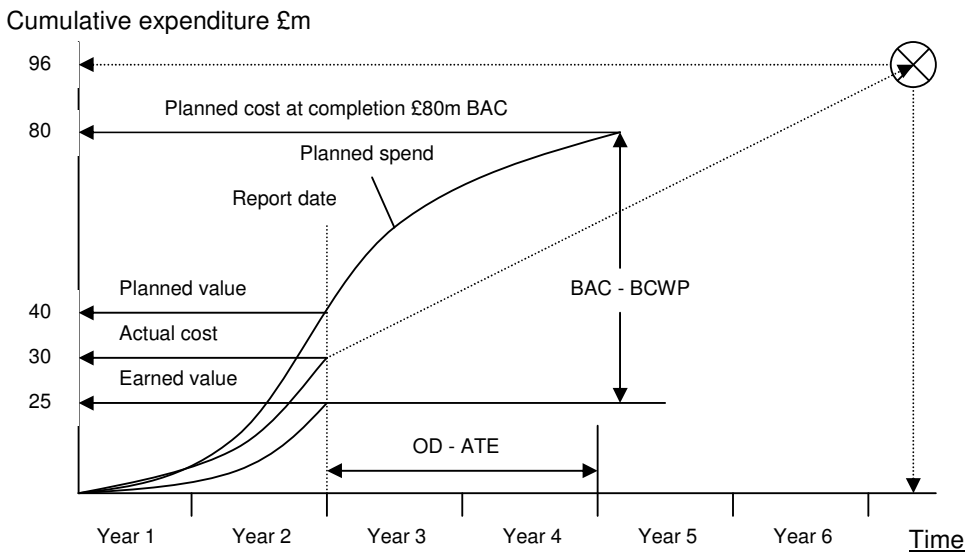
Source: Webb, 2003: 25

The calculations using these expressions are shown graphically in Figure 2.9.

5.3 Conclusion



A project is acquired based on the application of financial analysis of the scope and the work breakdown structure (WBS) on preliminary information (Humphreys, 1991: 471). A decision on a business proposition is based on techniques (financial ratios) being applied to information (Newnan *et al.,* 2004: 285). It is of significance to note the process of pricing and to document the results of all tenders as "lessons learned". More information on the use of historical data will follow.

6.0 MATERIALS

Materials are a key resource in almost any economic endeavour. Materials range from the simplest of raw materials to the most complex fabricated materials, with a large range in between (Barlow, 2006: 10). In most projects, materials are a key element. There are isolated instances where no material will be used for certain portions or elements of a project, but in most cases the use of material will apply. Materials must be procured at the right time and at the right cost in proper amounts in order to lead to an efficient production process (Dobler *et al*., 1990: 35).

Most materials compete on a number of characteristics including cost, availability, service life, weight, corrosion/wear resistance, workability, weldability and other ease-of-fabrication criteria. As the well-known phrase in the engineering community goes: "… there are no bad materials, only bad applications of materials…" (Barlow, 2006: 10). Strong performance of a material in a specific application may not guarantee similar performance in another application.

Opfer (2004: 3.1) comments that the automotive industry is a good example of continued competition among materials due to various factors such as weight with its attendant impact on fuel economy. Steel has been replaced in numerous applications in motorcars by high performance plastics and aluminum. In the beginning targets were non-structural elements such as interior panels and trim items. These non-structural applications have through further engineering migrated into structural components such as body parts and engine parts. Applications which traditionally made use of steel might still be using steel although the modern material will be a high strength low-alloy steel.

$$ETTC = ATE + \frac{OD - (ATE \times SPI)}{SPI}$$

$$2 + \frac{4 - (2 \times 0{,}625)}{0{,}625} = 6{,}4 \text{ yrs}$$

$$EAC = ACWP + \frac{BAC - BCWP}{CPI}$$

$$30 + \frac{80 - 25}{0{,}833} = £96m$$

Figure 2.9: Calculating the end conditions from the BCWS, BCWP, ACWP, CPI and SPI

Source: Webb, 2003: 27

6.1 Material handling

Material handling is a requirement of the production process. Inefficiencies in this area create plant wide problems. Poor materials handling can result in either damage to materials or the finished product (Thomas *et al.*, 2005: 810). An ineffective material

handling system can slow production down, creating other excessive costs due to delays.

Barlow (2006: 12) describes how early planning can make a difference, as well as the value of realising the importance of material identification in the early stages of the project to minimise lead times. He continues by stating that "… time is the enemy of flexibility in most projects". Figure 2.10 indicates the importance of early planning and also shows the trend in cost increase when changes to material specification are made at a later stage in the project.

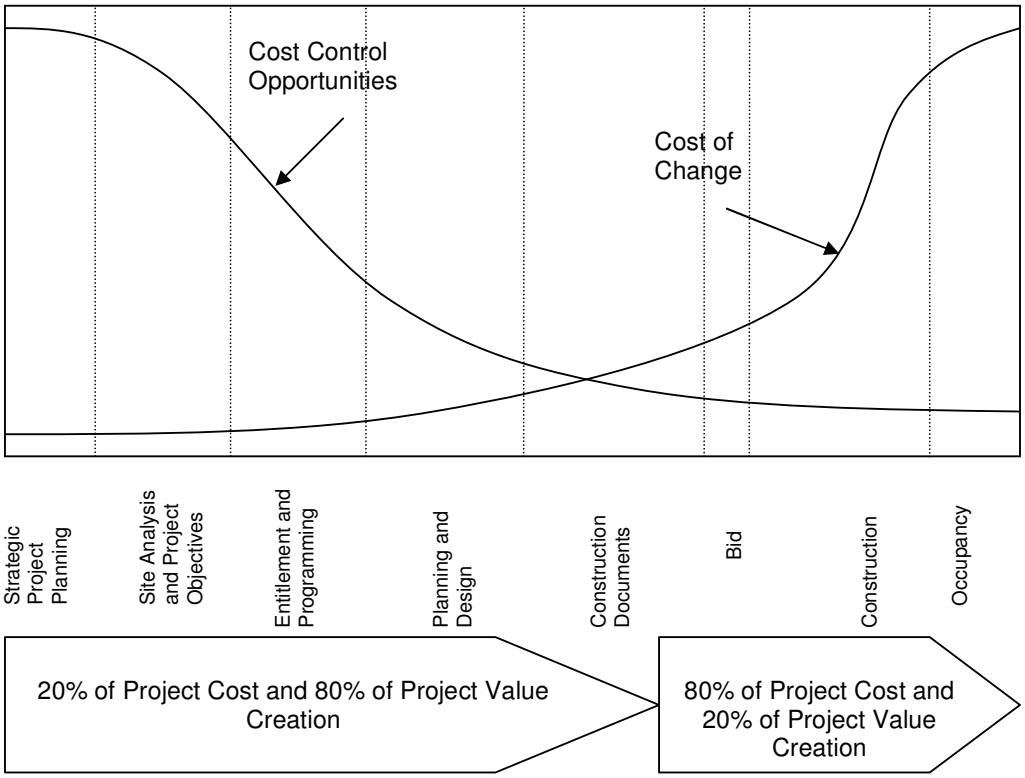


Figure 2.10: There are decreasing cost control opportunities and an increase in cost as the project progresses

Source: Barlow, 2006:12

6.1.1 Material handling principles

The handling of materials in construction differs depending on the location or the type of plant to be built (Thomas *et al.,* 2005: 810). The basic principles, however, remain the same. They include:

- Material movement should be over the shortest possible distance.
- Terminal time should be as short as possible.
- Eliminate manual material handling when mechanised methods are available.
- All materials should be identifiable and retrievable.

Mechanised material handling methods are most cost-effective in high-wage countries (Borowicz, 2007: 19). In a lesser developed country, the capital/labour trade-off given low wages will tend to emphasise manual methods rather than equipment-intensive operations. Meyer (1997: 72) and Eloff (2009: 13) pointed out that traditionally the circumstances in South Africa are no different. Bauer (2010 – Business Day, 15 July) and Mapenzauswa (2010: Mail & Guardian, 3 June) reiterate the extent of low wages in South Africa and that manual labour are more popular here than for instance in Europe, because of cheaper labour. Scott (2005: 4-7) refers to studies being undertaken to compare the cost of manual labour versus non-manual labour in South Africa.

6.1.2 Materials handling decision factors

Navon and Berkovich (2005: 1329) highlight the four basic decision factors affecting material handling:

- Material to be handled.
- Production system type.
- Facility type.
- Material handling system costs.

The second and third decision factor, as mentioned above, have more effect on a factory-type environment. These factors can more accurately be substituted by the type of plant to be constructed when considering the construction industry.

Material handling system costs and their economic feasibility will be dependent on labour costs in the capital/labour trade-off equation (Navon & Berkovich, 2006: 635). Predicted demand can assist in the economic and practical evaluation of alternatives.

6.2 Different material types

In most production/construction projects, material types can be segregated into four basic categories (Opfer, 2004: 3.1):

- Raw materials.
- Bulk materials.
- Fabricated materials.
- Engineered or designed materials.

Opfer (2004: 3.1) comments on the different types of materials. Raw material in construction refers to material in its most basic form and which require a minimum amount of processing to be useful. Examples of this type of material are sand, concrete, stone, etc.

Bulk materials are materials such as timber and steel and are most common on a construction site. Most of this type of material is readily available and if standard sizes are ordered the lead time is minimal.

Fabricated material is bulk material transformed into custom-fit items for a particular project. Steel pipe can, for example, be fabricated into a specific spool piece with specific dimensions to perform a certain function within a line. The same scenario can be sketched when considering structural steel members. Standard steel sections are cut and shaped to manufacture a specific member such as a column or beam with the relevant base plates, end plates, webs, ribs, etc. as per the structural requirement of the project.

The manufacturing process for fabricated material has some significance in this instance since it has economic implications and will impact on the pricing/costing procedure for the project. Chemical and process plant construction relies in most cases on specialists to detail each individual structural member, piping spool piece, etc. These specialists will take the design drawings and break it down to individual defined pieces. Pieces or members will then be detailed on shop details which will be used in a manufacturing workshop to produce a work piece as detailed on the drawing. These individual pieces will then be transported to the construction site. By making use of the

design drawings, members will then be bolted or welded together in a continuous process to take the complete project to commissioning stage.

Engineered or designed materials are those materials manufactured from different components to produce a piece of equipment such as an electrical distribution board, a centrifugal pump, an electrical motor, etc. In most cases these materials will be off-the-shelf items as the engineering team will strive to rather use such items than special design items, thus shortening the lead time. Standardisation in the case of engineered items is therefore desirable as a value-added principle to bring down costs. Costs will be less if one makes use of standard items rather than special items because of the principle of bulk supply/manufacture. Because of shortened lead times consequential damages can also be limited as far as possible.

6.3 Material purchase and management

Purchasing can be defined as the acquisition of necessary material for the correct quality at the correct time for a competitive price, from a selected vendor or supplier (Opfer, 2004: 3.5). Sufficient stocks of material will prevent costly delays.

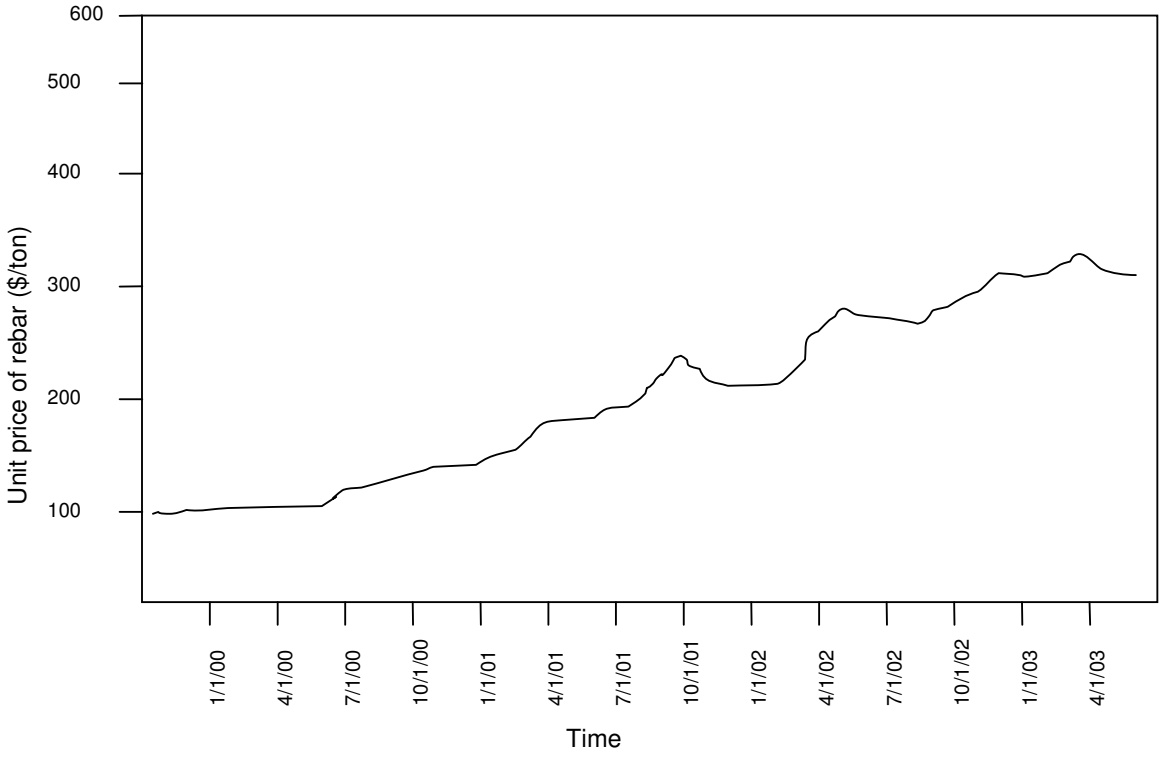

Figure 2.11: Price fluctuation on reinforcement steel in the Turkish construction industry during the period January 2000 to April 2003

Source: Polat and Arditi, 2005: 700

Figure 2.11 from the research conducted by Polat and Arditi (2005: 700) illustrates the price increase on reinforcement steel in the Turkish construction industry for the period January 2000 to November 2003.

Polat and Arditi (2005: 700) extended their research by also investigating the use of reinforcing steel in the Turkish construction industry for the period 1997 to 2002. Figure 2.12 depicts the results.

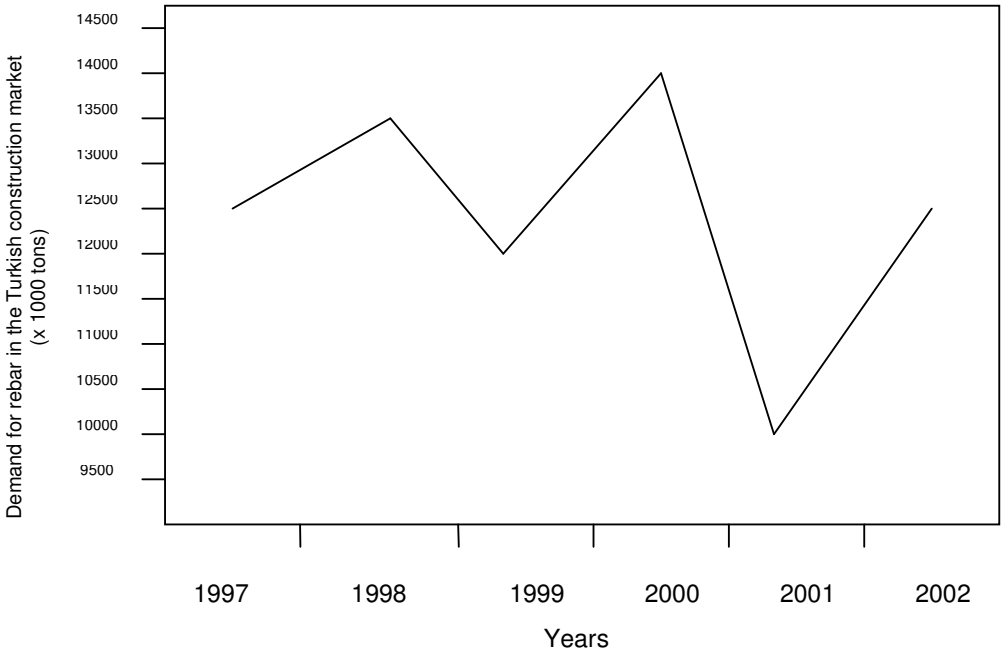

Figure 2.12: Demand fluctuation of reinforcing steel in the Turkish construction market for the period 1997 to 2002

Source: Polat and Arditi, 2005: 700

A comparison of Figure 2.11 and Figure 2.12 shows that although there is a basic economic principle in that the higher the demand the more the price will increase, in construction this will not always be the case. The steady increase in the steel price can be noted in Figure 2.11, irrespective of the demand (Figure 2.12).

6.3.1 Material management

The typical stages of an Engineer/Procure/Construct (EPC) contract is described by Kini (1999: 30-34) as follows:

- Planning – The project team should create and maintain a plan as to how they foresee the execution of the project. In doing this they engage into a psychological process of thinking about the activities required to create a desired goal on some scale. EPC projects are normally lump sum projects constructed on a turn-key basis which makes planning even more important.
- Preliminary design – It will be necessary to do a preliminary design to compare different design possibilities and options to obtain a design philosophy from which the final design can take place.
- Final design – Final or detailed design is the process where the complete project gets designed in the finest detail to allow the contractors to have specifications and drawings to execute the work on site.
- Procurement – Procurement of the material and equipment that will be required to construct the plant. Particular emphasis is placed on long lead items which may impact on the planned end date.
- Vendor control – Vendor selection, appointment and management is necessary to ensure that material and equipment is delivered on time.
- Construction – In the construction phase the material and equipment that was procured must be re-worked to fabricate the designed details and these fabricated items must then be installed on site and connected so that all is in a functional state.
- Close out – As material and equipment gets delivered to site and fabrication and installation take place, constant quality control ensures consistency in quality. As the different portions of the plant are finished, it will be commissioned to make sure all is as per the design. The final step in closing out of the project is to make sure that all final drawings, specification and design packs are delivered and checked against the actual installation.

Material management is an important part of construction and if well conducted can have a significant effect on project costs. Kini (1999: 30) notes that 50% to 60% of project costs relate to the material/equipment. Implementing a proper material management system therefore makes sense. Navon and Berkovich (2006: 635) concur with these findings. Figure 2.13 illustrates the interaction of a typical supply chain for material for a construction project.

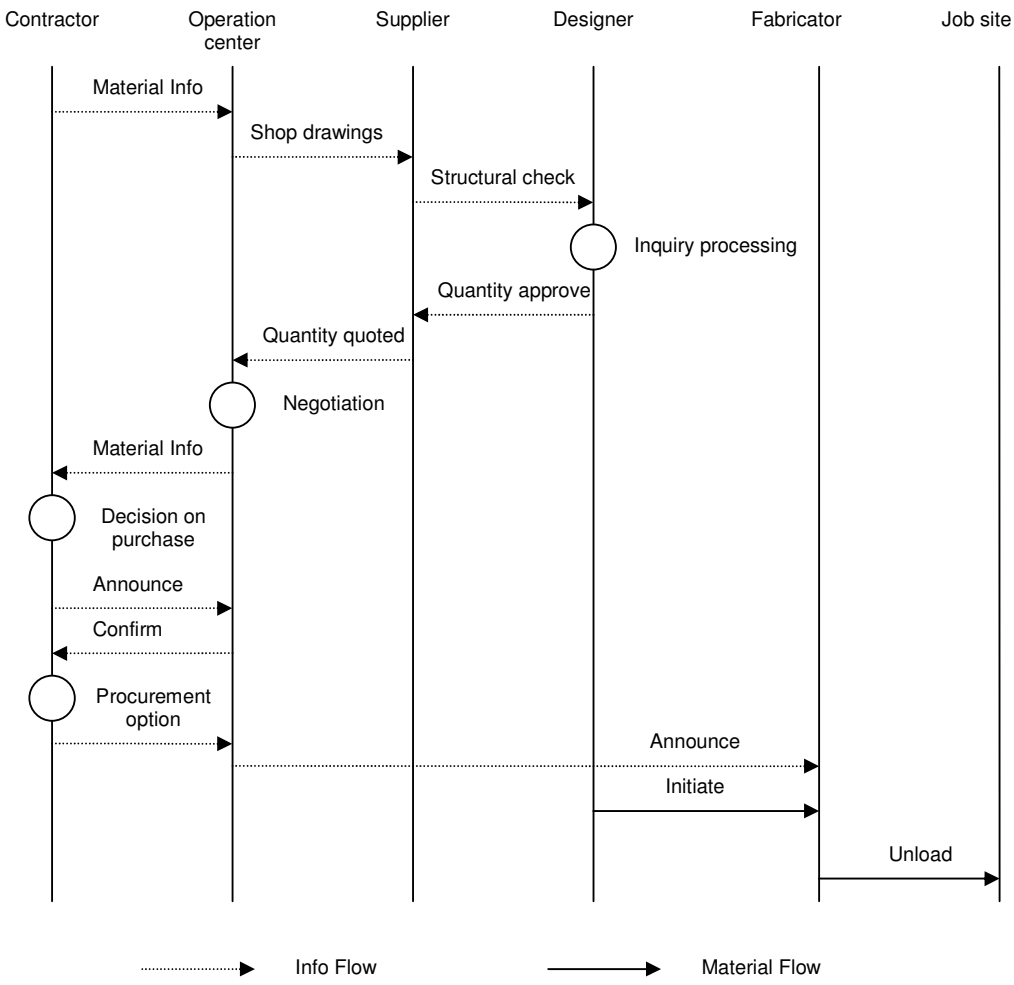

Figure 2.13: Interaction diagram for a typical supply chain of construction materials

Source: Castro-Lacouture and Skibniewski, 2003: 795

6.3.2 Material quality

All material should be procured against a standard set of predetermined standards or specifications. Over-specifying material will lead to increased costs (Sterner, 2000: 393). Higher specification in material is not necessarily always a good advantage to have, especially when considering the added cost to the project (Flanagan *et al.*, 2001: 53).

Poor quality material, on the other hand, might lead to material failure or high levels of fatigue which will eventually lead to failure. This will obviously lead to additional expenses in replacing the material in question and will thus end in rework. This means

that not only will the material have to be replaced, but there will also be additional labour costs and sundry overhead costs involved.

6.3.3 Material traceability

In some cases it is necessary for the raw material supplier to produce milling certifications to prove the quality of its raw material and that the material meets the standards that are required. Bulk materials might also be exposed to these requirements. The supplier of piping material, for instance, used to manufacture a certain spool piece might have to prove that its piping adheres to the set specification required (Barlow, 2006: 12).

6.3.4 Vendor surveillance

Vendor surveillance is especially important when dealing with fabricated and engineered materials. Quality control might indicate certain hold points during the manufacturing process of these types of materials and inspections (surveillance) will be required to ensure that the manufacturer meets the required standards and specifications (Lu & Anson, 2004: 218).

6.3.5 Material quantity

Acquisition of materials on any project may pose some logistical and practical problems for the company employed to construct the plant. Material quantity will have to be a well-balanced act to optimise costs in this regard. Under-ordering of materials will lead to stoppages in construction which will be costly (Barlow, 2006: 11); especially if the crews at hand have to accelerate to catch-up to the agreed programme. Ordering too little of a certain material will also have the effect that the discount from the supplier might be less due to the smaller order. Over-ordering will have the effect that storage might become problematic, not only because of space requirements but also because of added costs to the project (Miltenburg & Pong, 2007: 1643).

Some financial losses may be recuperated on resale of excess material but in most cases this material will be considered to be “second-hand” and will not reach the same price as the initial purchase price, thus resulting in a loss. The loss of interest will add to the total financial loss on material. Some materials, cement for example, can only be stored for a limited period of time. If this type of material is used beyond the acceptable

selling date it will have a negative effect on the quality of the end product (Kumar, Nottestad & Macklin, 2007: 143).

7.0 LABOUR

Each task is directly connected to a certain effort by certain employees to complete this task (Perry, 2006: 402). When conducting an estimate, management must know how long certain tasks will take to complete and what the cost implications will be to pay for the labour to accomplish a task (Whiteside, 2006: EST.08.3). The monitoring of progress and a good understanding of the cost factors will therefore be essential to controlling costs (Stenzel & Stenzel. 2003: 37-38).

7.1 Labour classification

There are basically three classifications of labour contributing to the final labour content of a project (Borowicz, 2007: 19):

- Direct labour: The labour directly involved in building or producing a certain product or installation.
- Indirect labour: This form of labour includes activities which will not become part of the final installation but is required to complete the project as a whole.
- Overhead labour: Labour that cannot be charged or identified with a specific piece of work and must therefore be allocated on some arbitrary basis, or be handled as a business expense irrespective of the quantity of work.

The role assigned to certain classifications of labour might alternate from project to project. On smaller projects it might not be feasible to appoint specific administrative personnel. These tasks will then be handled from head office. Larger projects might look at dealing with these tasks on site. These costs will then form part of the site establishment and might be treated as indirect labour rather than overhead labour.

A boom in construction also requires more labour to construct new projects. Ziguras (2006: 204) refers to the situation in Australia. Anonymous (2008a: 4) and Palmer and Hughes (2008: 3-4) refer to the labour and skills shortage in the United Kingdom. Anonymous (2006a: Business Week, 27 March 2006) also refers to the shortages of labour in China and how this is influencing the wage rates there.

7.2 The cost of human resources

The focus of this study is more directed to direct costs than indirect costs, but it is nevertheless necessary to understand the importance of indirect costs and the effect it might have on the cost philosophy in general. More and more human resource management activities are evaluated in economic terms (Ahn & McLean, 2006: 262). In the current climate of rising personnel costs and rising costs for energy and raw materials, estimates of expected costs and benefits are expected (Buchner, 2007: 60).

7.2.1 Human resource accounting

The inauguration of an efficient human resource accounting system will be the first step in developing a sophisticated measurement system that will enable the firm to report accurate estimates on the worth of the human assets of the organisation (Carmeli & Weisberg, 2006: 191).

7.2.2 Value to the organisation

Gilbreath and Montesino (2006: 565) indicate that one alternative to measure the historical cost of an employee is to measure the cost of replacing that employee (Shafritz, 1992: 23). In professional sports, the value of an athlete's services is often determined by how much money a particular team, acting in an open market, is willing to pay for his or her services. The same can be said of employees competing for work in the open market (Gilbreath & Montesino, 2006: 567).

Advocates of human resource accounting make a strong and compelling case for the need of measurement of replacement cost and employee turnover cost (Innes, Kouhy & Vedd, 2001: 17). Cascio (1982: 6-7) points out that these measurements tend to ignore the fact that monetary values cannot always be attached to the information that is collected. Perhaps the most significant limitation is that these measurements only measure inputs and not effectiveness.

7.2.3 Costing employee behaviour

The general idea of costing human resources is not a new one. A classic article by Brogden and Taylor (1950: 133) addressed the potential for developing on-the-job performance criteria expressed in dollars. They noted:

> *"The criterion should measure the contribution of the individual to the overall efficiency of the organization. It centers on the quantity, quality and cost of the finished product. Such factors as skill are latent – their effect is realized in the end product."*

The contribution each employee makes is not related to the size of the firm's investment in an employee, but is directly related to how each person works and what is produced (Cascio, 1982: 6-7).

7.3 Development of labour rates

Basic wages constitute the portion of the labour rate which will go directly to the employee. Base wages are usually reported on a time basis and will be expressed in hour, week or month. Craft labour is normally expressed per hour whereas supervisory labour is expressed per week/month (Borowicz, 2007: 19).

The extent to which overtime will be worked on a project depends on the programme or time frame in which the project must be completed. The extent to which overtime is worked will influence the labour cost for the project. The increased cost in labour for working overtime is offset against the earlier completion of the project.

The calculation of indirect labour cost can be done by making use of primarily two methods – direct estimate and historical data (Pickett & Elliott, 2007: EST.02.2). The direct method lists the resources needed to complete the project. Each of these resources is then priced out to determine the total cost. Alternatively, historical cost data can be used and by doing this the estimator can base his costing on previous completed projects (Pickett & Elliott, 2007: EST.02.2).

7.4 Estimating hours to complete a task

Each task constitutes a certain labour input to take the task to completion. According to Thomas (2006: 36), a time study can be applied to establish the duration of each task. Thomas (2006: 36) also refers to the methodology of these time studies and Finlay, Norman, Stolberg, Weaver and Keane (2006: 233) comment on modern methods of keeping time for tasks completed. Ampt, Westbrook, Creswick and Mallock (2007: 18-24) use time studies to establish the labour content of a task.

Depending on the level of information available, the estimator can group the quantities in the appropriate work packages and working with the planners start to develop the work package sequence. By making use of databases (Pickett & Elliott, 2007: EST.02.2), the estimator can then apply a time factor to the work packages and also add the overall staffing content.

7.4.1 Work break-down structure (WBS)

The importance of Work Break-Down Structure (WBS) is emphasised by Hewitt (2006: EST23.1) and Zhao (2006: RISK05.1). Labour estimates are based on material quantities and will therefore only come into play at a more advanced stage of the project. The first step is to break the project down into meaningful packages (work break-down structure) (Humphreys, 1991: 471).

Determining the hours it will take to construct a certain portion of work can be done by consulting a database where time durations are captured. These databases are based on actual historical projects and should be kept up to date on a regular basis (Pickett & Elliott, 2007: EST02.1). Alternatively, time-cost studies can be used. This method is based on the observation of a team of workers working on a specific piece of the construction (Ampt *et al.,* 2007: 18-24). The time spent to complete the work gets recorded and priced.

7.4.2 Cost to support the worker

As previously mentioned there are also indirect and overhead costs which need to be taken into account since direct labour alone will not complete the project. The pricing methodology of these costs has been discussed previously by Borowicz (2007: 19). The most important aspect here is to make allowance for these costs and to include it in the estimated final cost irrespective whether a percentage method or a detailed calculation is followed.

7.4.3 Factors affecting productivity

Carrell, Kuzmits and Elbert (1989: 74) define productivity as follows:

> *"Productivity is the ratio of some measurable unit of output to some unit of input. Productivity is therefore a measure of efficiency, or the*

amount of work that the employees accomplish during each working day."

Whiteside (2006: EST.08.1) demonstrates that in a perfect world, perfect productivity (1.0) would be accomplished in a 40-hour work week, with everyone taking all their holidays and vacation days as planned. All of the engineering drawings would be 100% complete, there would be no delays of any kind, everyone would work safely, everything would fit perfectly the first time, the weather would be perfect and there would be no litigation at the end of the project.

Whiteside (2006: EST.08.3) also describes the effect of labour legislation on productivity and how jurisdictional rules have an impact on productivity. Figure 2.14 shows a productivity graph of a specific craft mix performing a specific task, but taking more time due to the effect of labour law preventing the same craft to perform more tasks.

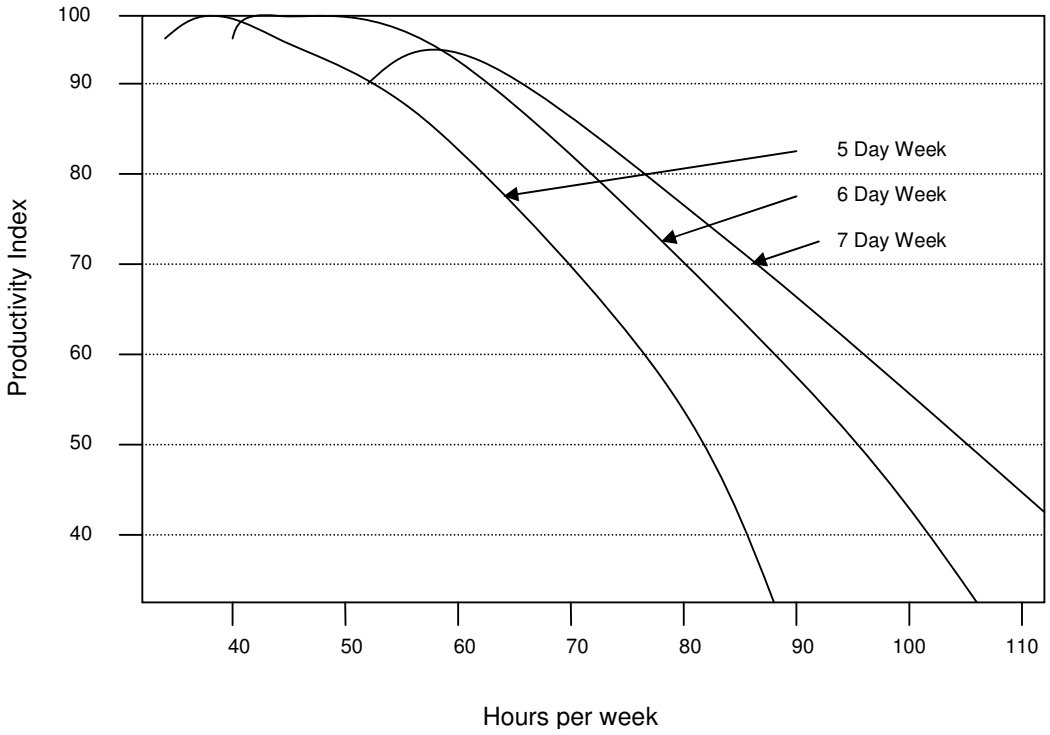

Figure 2.14: Productivity index versus hours per week
Source: Whiteside, 2006: EST.08.3

How much work can be completed in a specific time frame? This is a frequently asked question when costing the labour content of a project. Optimising the labour efficiency is one of the biggest challenges for management to make labour more cost-effective (Boyle, 2007: CDR.02.1).

In America, for instance, the "Houston-Gulf Coast Indices" are used in the petrochemical industry. These indices provide the estimator with a base time to complete a specific task. Adjustments for variables will then be needed to improve the indices according to the specific project specifications/conditions.

When pricing the labour cost of the project the estimator should look into the following since these factors will influence the price for labour (Fayek & Oduba, 2005: 939).

- Is sufficient skilled/unskilled labour available in the area?
- If the site is remote, will labour have to be transported to and from work?
- Weather conditions?
- Public holidays?
- Living quarters or living out allowances?
- Will overtime be required and to what extent?
- Political situation of the area in which the project will be constructed?

Boyle (2007: CDR.02.1) continues to describe some design factors and management factors that will also influence productivity. He points out, for instance, that vertical construction is more complex than horizontal construction. The effect of disruption of work on productivity is also discussed.

On repetitive tasks, in particular, the learning curve for labour increases as each task gets finalised. As the crew gets more and more involved in a certain task they become more efficient working together with familiar tools, or in many cases special tools for specific tasks.

Thomas, Riley and Messner (2005: 811) indicate (as per Figure 2.15) the daily productivity curve of a specific construction team with the different factors affecting this team's productivity.

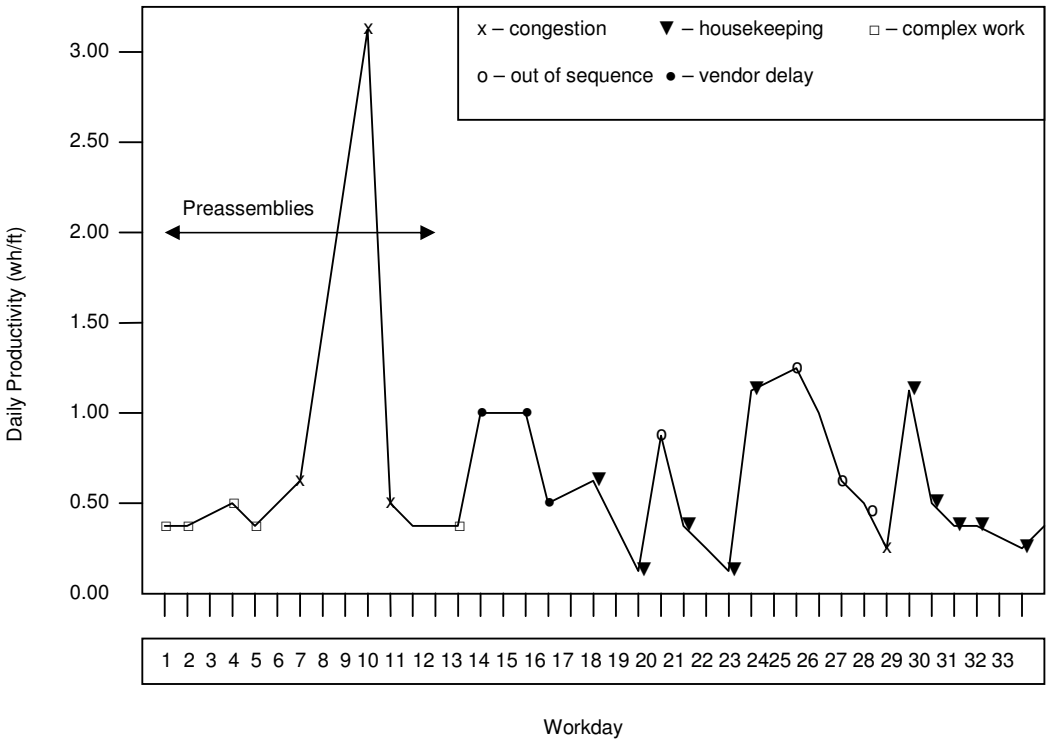

Figure 2.15: Productivity of a construction team with the different factors affecting their productivity

Source: Thomas, *et al.* 2005: 811

A similar illustration of how productivity fluctuates during the course of a construction project can be seen in Figure 2.16 where Whiteside (2006: EST.08.4) plotted a resource loaded productivity curve. Ewing and Thompson (2007: 356) also comment on the measurement of productivity over the time span on a project.

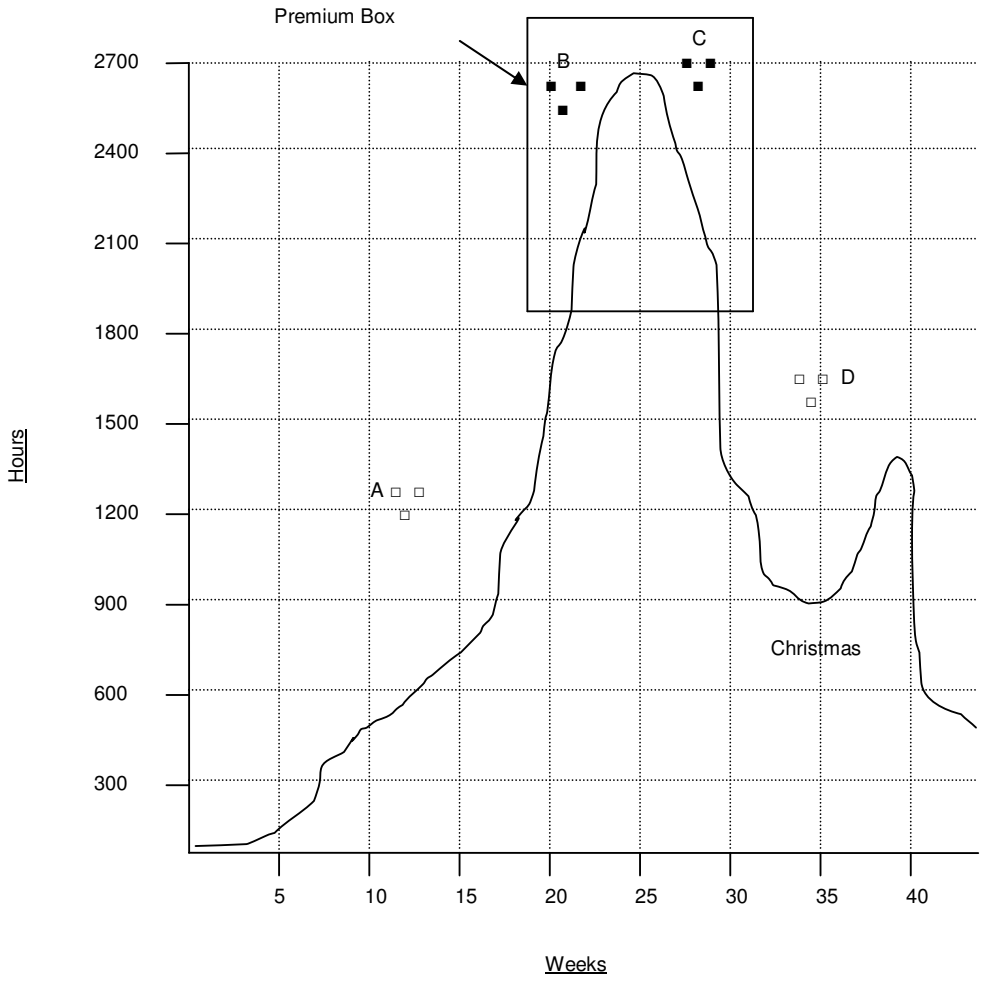

Figure 2.16: Resource loaded curve

Source: Whiteside, 2006: EST.08.4

7.5 Performance monitoring

Coetsee (2002: 7) describes the concept of performance as follows:

> *"Performance is the realizing of goals, agreed upon or set by the individual for himself and meeting its own expectations or those of other people, such as managers or colleagues, to whom a product is delivered or to whom a service is rendered."*

Work output and the costing thereof are addressed in activity-based cost (ABC) methodology (Anonymous, 2008e: online). This system has been developed to assist in organising, analysing and setting-up labour monitoring systems. Activity-based

costing is mainly done by making use of a work break-down structure (Grandlich, 2004: online; Katz, 2002: online). The labour estimate is usually the basis for project performance monitoring.

The comparison of actual work hours expended, versus the estimated work hours and the development of a relationship between milestone goals, is a key tool in determining how much of the project is completed (Pickett & Elliott, 2007: EST.02.2). How much of the project has been expended to get to the current point and if there are any problems, what has to be worked on to overcome these problems? Most importantly, how will this affect the completion date and final costing?

As previously stated in this chapter, different indicators exist to indicate the performance of the project, such as the two provided below. Although these indicators can be used to track a complete project's progress, they can also be used to track portions of work.

CPI (cost performance indicator) = hours earned/hours expended (Patiro, 2007: online; Reh, 2008: online; Weber & Thomas, 2005: Paper presented by the Ivara Corporation).

and

SPI (schedule performance indicator) = hours earned/hours planned (Lipke, 2005: Unpublished paper presented by Lipke; Lipke & Henderson, 2006: 5).

In any event, if the value obtained in the above formulas is "one" or more than "one" it means that the project is on or ahead of cost and/or schedule (Humphreys, 1991: 501). A value below "one" will mean that this portion of work will need some attention to make it perform better. It is, however, important to note that should the critical path be behind schedule and all the other indicators are above "one", the project will still be in trouble and will finish late (Anonymous, 2008g: online).

Earlier in this chapter the summarised explanation of work sampling was mentioned. Work sampling entails the monitoring of time spent on a certain activity (Finlay *et al.,* 2006: 232). By making use of the unit cost per employee, work sample can be priced to determine the labour cost for the activity. These time studies and costs will then form part of a database to be used on future estimates. Frequent studying of the same type

of activity will lead to improved data which in turn will lead to improved estimates (Pickett & Elliott, 2007: EST02.2).

8.0 ENGINEERING AND DESIGN

Flemming and Koppelman (2009: 24) defined engineering as follows:

> *"Engineering is the discipline, art, skill and profession of acquiring and applying scientific, mathematical, economic, social, and practical knowledge, in order to design and build structures, machines, devices, systems, materials and processes."*

The success of a project is to a large extent dependent Houston-Gulf Coast Indices on the engineering done in the design of the project. Improved engineering is continuously required to be more competitive, especially in an increasing global market. Globalisation, according to Lucena (2006: 322), has caused trade barriers to fall away and adequate engineering is not enough anymore (Becker, 2006: 262). Engineering has to be such that it can compete internationally (Lucena, 2006: 322).

The new trend (or at least for the past couple of years) is to outsource the engineering effort to more experienced companies on a global playing field (Becker, 2006: 262). In the case of large firms with global offices the engineering can be kept within the boundaries of the firm's own experience, but the increasing level of technology and engineering involved in the construction of petrochemical plants necessitate the involvement of specialised firms (Lucena, 2006: 322).

8.1 Engineering and design of new processes and projects

The design of new processes and projects may take years to complete depending on the level of engineering required and the technology used. New technology requires more research and development, thus resulting in extended time frames. Anonymous (2007a: 30) refers for instance to the Pebble Bed nuclear power technology currently taking shape in South Africa. According to Anonymous (2007b: 545), Ireland is also investigating this technology.

8.1.1 Pure and applied research

In the petrochemical industry constant research is required to develop new or improved products. The results of such research will eventually lead to either alteration to existing plants to produce the improved products or the construction of new plants to introduce the new product in the market place. New products, improved products or more economic methods to put a specific product in the market, all have financial benefits to the developer. It is therefore a constant goal of the researcher to strive towards perfection in these fields.

Pure research is mostly undertaken by universities and institutes and does not produce a particular end product. It is therefore not applied with the aim to design a specific product but rather an investigation into the interaction between different chemicals, for instance.

8.1.2 Life cycles

The life cycle of a project will have significant influences on various aspects of the design of the project (Humphreys, 1991: 125; Sterner, 2000: 387; Life Cycle Costing, 2008a). Methodology and material are but two factors that will be involved in the extension of the life cycle of a project. Different parts of plants will also have different life spans (Flanagan & Norman, 1983: 12). The civil infrastructure, for instance, will have a far greater life span than some of the mechanical equipment.

The life cycle of a plant should be predetermined and incorporated in the design of the plant (Ashworth, 2004: 350). If the product of the plant will be obsolete in five years it will not make sense to construct a plant that has a life span of 30 years. The prediction of market conditions and the forecasting of market reactions to new products is a difficult process and in many cases go hand-in-hand with risk (Figure 2.17 and Figure 2.18). Newnan *et al*., (2004: 37) indicate that the time to consider all life cycle effects, and make design changes, is during the needs and conceptual/preliminary design phases.

A good example of market reaction to a product is the reaction from the public and concerned environmental groups to the proposed development of nuclear power plants in South Africa (Anonymous, 2007a: 13; Anonymous, 2007c: 141; Reina, 2006: 18). Many believe that these plants' advantages (Wicks, 2007: 37-38) will far exceed any

disadvantages (Anonymous, 2007d: 13; Tuffs, 2008: 13), but the resistance from society should be reduced to prevent future complications when funds might have been expended which might result in losses. A similar situation is currently being played out in the bio-fuels field in South Africa (Anonymous, 2006b: online; Anonymous, 2008c: online; Anonymous, 2008d: online; Creamer, 2008: online).

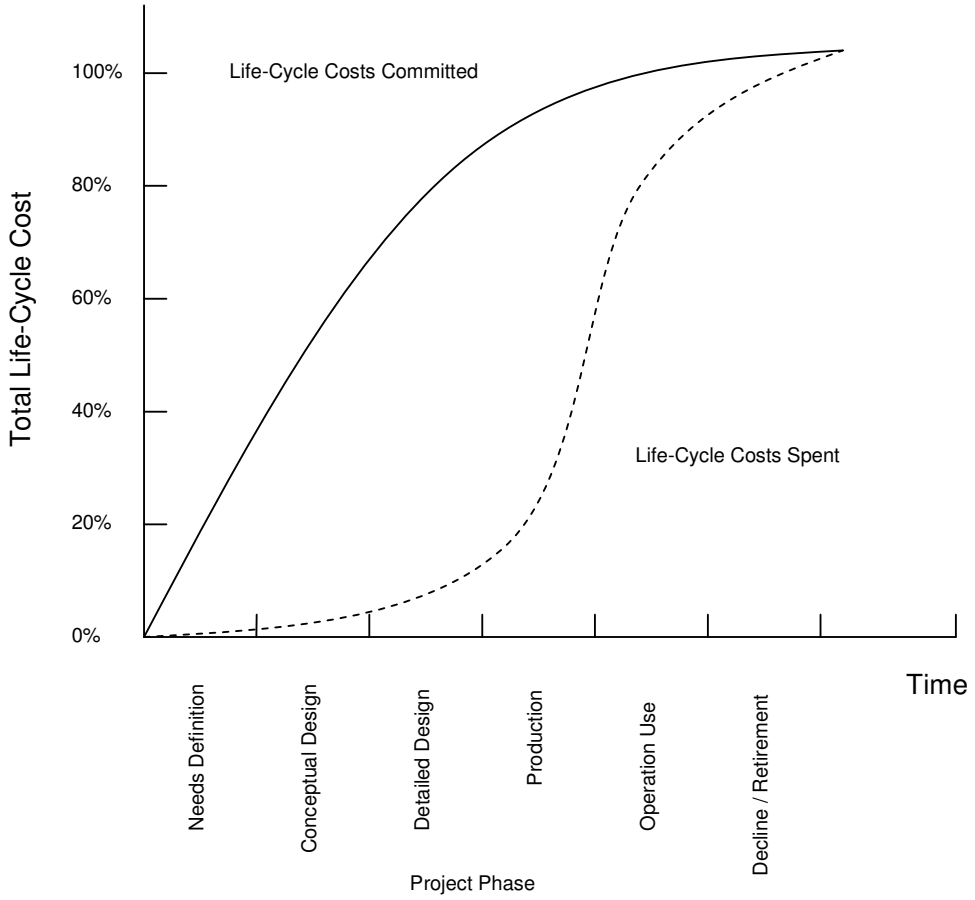

Figure 2.17: Cumulative life cycle costs committed and dollars spent

Source: Newnan *et al.*, 2004: 37

8.1.3 Computer aided design (CAD)

The engineering and design of plants is to a large degree dependent on computer aided design (CAD) or computer aided engineering (CAE) (Pratt, Anderson & Ranger, 2005: 1251). The inclusion of computers in the design of plants is, however, not a new trend and has been used for many years now (Karshenas, 2007: IT.06.1). New and improved software is constantly available in the market. This new software enables the

designer/engineer to improve his design and in most cases do it in less time which is always favourable (Pratt *et al*., 2005: 1252).

As previously mentioned, the globalisation of the construction industry and engineering is an increasingly popular method to construct plants (Becker, 2006: 262). The use of computers and computer aided design packages makes globalisation much easier (Anonymous, 2008b: 4). Electronic correspondence and interaction via the Internet makes distance between offices a minor inconvenience rather than a major obstacle (Shah, Jeon, Urban, Bliznakov & Rogers, 1996: 348).

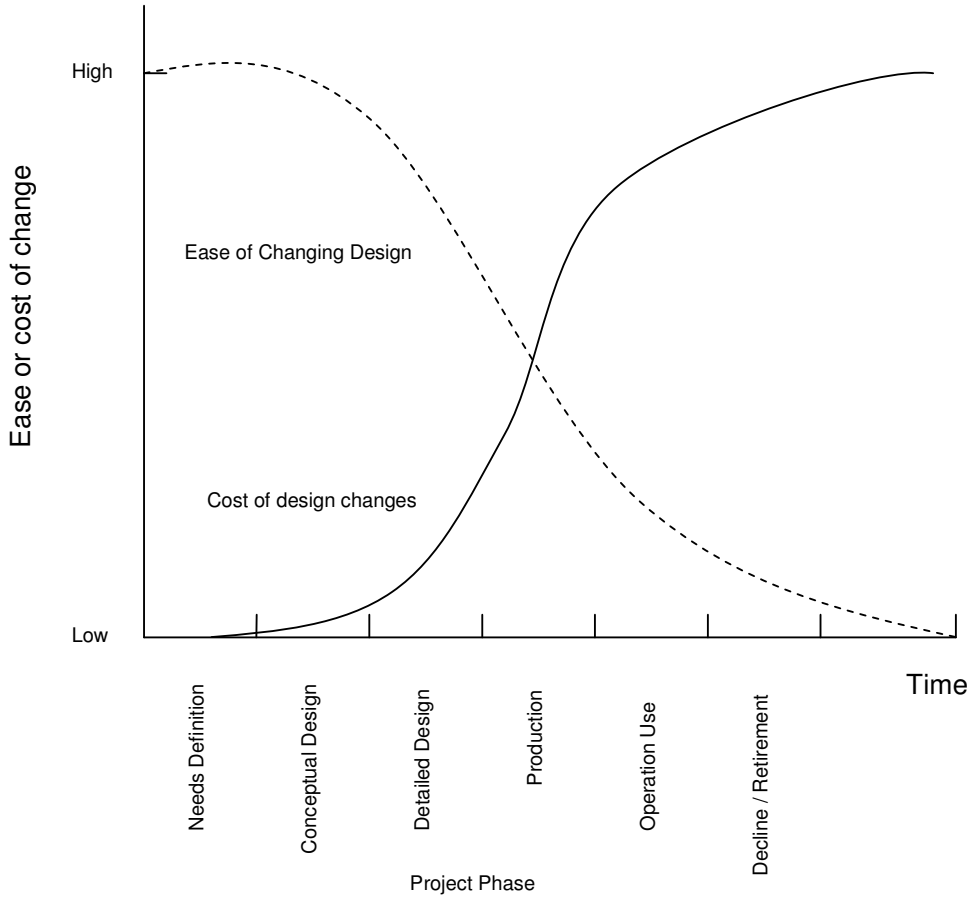

Figure 2.18: Life cycle design change cost and ease of change
Source: Newnan *et al*., 2004: 37

8.1.4 Prototype plants

Prototype plants or pilot plants are generally constructed in the event of new technology that needs to be tested before being put into action as a full-blown production plant (Voronin & Prokhorov, 1993). Prototype plants are expensive to build, but are cost-effective in the long run as savings are indirectly instigated in the construction of the production plants (Anonymous, 2008f: online). A prototype plant is generally a simulation of parts of the complete process or it can be a full small-scale plant built to function and operate as the production plant. Prototypes can either be actual small plants or computer simulations (Revkin, 2005: New York Times, 7 December 2005).

8.2 Project and process design

Peters *et al.,* (2003: 72) indicate that often in the process creation step, after elimination of the less profitable processes, several entirely different flow sheets for the manufacture of the same product can still be used. These processes must be compared in order to select the one that is best suited for the existing conditions. The availability and cost of several factors will lead to the best process being selected. These factors include the following:

- Technical factors.
- Raw materials.
- Waste products and by-products.
- Equipment.
- Plant location.
- Time factor.
- Process consideration.

The design team should never lose sight of the practical limitations involved in a design. It may be possible to determine an exact pipe diameter for an optimum economic design, but it does not imply that this exact size must be used in the final design. If the optimum diameter is something other than a stock size, it will in most cases be impractical to have this pipe purpose made and it will likely cost more.

The basis of an optimum economic design will be that, should there be two or more methods obtaining exactly equivalent final results, the preferred method is the one involving the least total cost. One typical example of an optimum economic design lies in determining the pipe diameter to use when pumping a given amount of fluid from one point to another. The same final result can be accomplished by using an infinite number of different pipe diameters. The pipe to be used should be the one leading to the least total cost. The total cost will be represented by the total of the cost for pumping and the cost to install the piping system. A graphical representation showing the meaning of an optimum piping design can be seen in Figure 2.19.

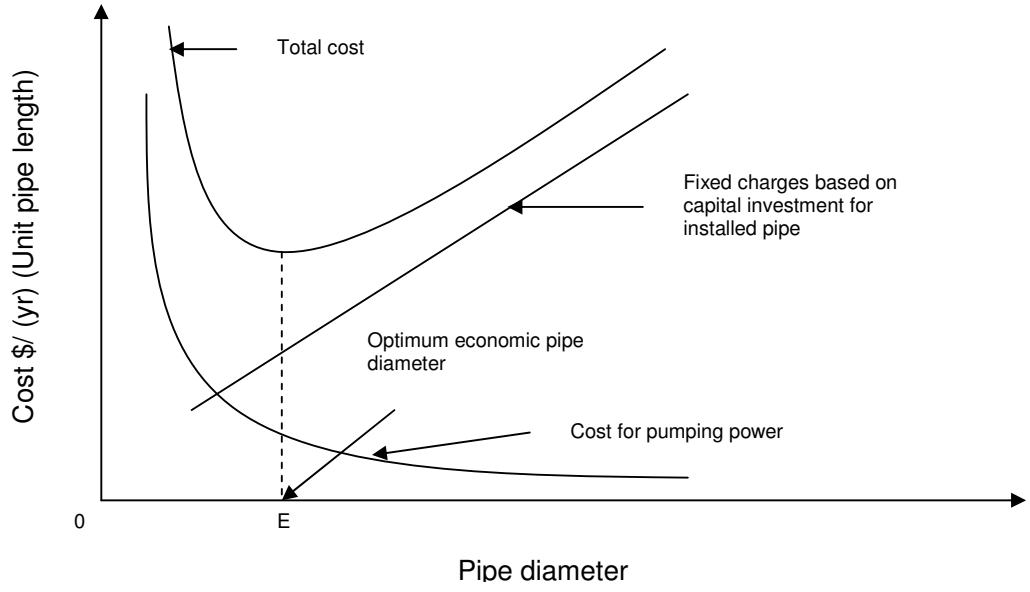

Figure 2.19: Optimum economic pipe diameter for a constant mass-throughput rate

Source: Peters *et al.*, 2003: 9

Payne (2007: CDR.03.1) refers to the implications of poor design documentation and how this may lead to claims from contractors.

8.2.1 Standardisation

Standardisation is an attempt to base designs, as a whole or in part, on similar designs. By doing this the availability of material, expertise, labour skills, etc. become more readily available, thus making the process more cost-effective. The inclusion of existing and tested technology into a new process or plant will also reduce the costs further in the sense that these portions of the plant will not have to be re-designed.

A good example might be found in the inclusion of diesel engines to drive pumps, compressors, etc. on a given plant. The output of one type of engine can, for instance, be changed by adding turbo chargers to the engines as to normally aspirated engines and by doing so altering the horse power output of the engine. Engine displacement can be varied by changing the stroke and holding the cylinder bore constant. In this example one type of engine is used in various functions on a particular plant. The advantage for plant maintenance is that engine parts will be similar on these engines resulting in a more simplistic maintenance programme, making it more cost-effective. The previously mentioned learning curve of labour craft (maintenance teams in this case) will also be improved by this procedure.

8.2.2 Process selection

Although process selection is not crucial to the costing of a project it will influence design which will ultimately influence the construction cost of the project. Process selection is normally driven by factors such as reliability, safety, environmental impact and economics. External factors such as current/future markets for products produced by the plant also plays a role, but will surface in the feasibility study (Peters *et al.*, 2003: 72).

8.2.3 Manufacturability

Design must not only focus on product design, but also on manufacturing the design. Manufacturability refers more to factory-based product manufacturing rather than project construction.

8.2.4 Constructability

Constructability, on the other hand, refers to the construction of a project (Anders & Lars, 2007: 113). The design may look good on paper and may work well in a simulation, but the practical construction of the design might pose problems. Opfer (2004: 5.4) describes constructability as the optimum use of construction knowledge and experience in planning, design, procurement, and field operations to achieve overall project objectives.

9.0 SUMMARY

Advances over the past two decades in the level of understanding of chemical principles and process plant design, combined with the availability of new techniques and computer-based tools, have led to an increased degree of sophistication that now can be applied to the design of chemical and bio-chemical processes.

In order to construct feasible plants, it is essential to understand the total cost control philosophy surrounding the construction of these plants. The development of a new process or plant from concept evaluation to profitable reality often is a very complex operation. Understanding the basis of the cost implications will enable the student of the economic principles surrounding plant feasibility and profit analysis, to grasp the importance of the relevant influences on these factors.

Muscianesi (2003: 2), Lukas (2006: EST.03.1) and Harbuck (2007: EST.16.1) indicate that at the beginning of a project, cost is the first concern. The estimator is selling his project price to his management (Postula, 2004: 1.1). In many cases, after this sale, costs drop to a much lower position on the project priority list. Other project commodities such as schedule (Aslaksen & Vigerust, 2007: RISK.02.1), safety (Tuffs, 2008: 13), constructability (Lam *et al*., 2007: 36), etc. then take precedence.

Scott (2006: New York Times, 16 June) indicates that in a highly competitive bidding market, and especially in an economic construction recession, project pricing is forced down by market conditions (Hill, 2006: 347). This and the current tendency of larger employers in South Africa to award contracts on a “lump sum” basis, shifts the importance of cost from the employer to the contractor (Van Niekerk, 2008: personal communication). This makes it even more important to understand cost and why it is important to control costs on any project (Patterson, 2006: IT.05.1; Lucas, 2007: OWN.05.1). Profit forecasting (DiMonica, 2006: 10) begins at project level (Tague & Morrison, 2007: 12).

Cost is the value of an activity or an asset (Azhar *et al*., n.d.: 1). Generally this value is determined by the cost of the resources that are expended to complete the activity or produce the asset. Resources utilised are categorised as material, labour, plant and indirect costs. Money and time are often considered to be resources but they only implement and/or constrain the use of the physical resources (Postula, 2004: 1.1).

To determine the cost of a plant or the proposed profitability of the plant, it will require getting involved in pricing the project. Pricing can be described as the process by which the cost of a project is established. It refers to a set of tools and techniques which can be used in the costing process. Some of these tools would include pricing strategies, sales and revenues, return on investment, return on sales and break-even analysis.

Material purchases form an approximate total of 60% to 80% of the total plant value – depending on the type of plant. It is therefore important to emphasise control over material. Materials are a key resource in almost any economic endeavour. Materials range from the simplest of raw materials to the most complex fabricated materials with a large range in between (Barlow, 2006: 10). In most projects, materials are a key element. There are isolated instances where no material will be used for certain portions or elements of a project, but in most cases the use of material will apply. Materials must be procured at the right time and at the right cost in proper amounts in order to lead to an efficient production process (Dobler *et al*., 1990: 35).

Current labour law and legislation, together with the human factor surrounding project execution, force the project team to consider the consequences of labour and human resource management. More and more human resource management activities are evaluated in economic terms (Ahn & McLean, 2006: 262). In the current climate of rising personnel costs, as well as rising costs for energy and raw materials, estimates of expected costs and benefits are expected (Buchner, 2007: 60).

Before the effect of material and labour can take effect on the total project cost, the project must be designed. The success of a project is to a large extent dependent on the engineering done in the design of the project. Improved engineering is continuously required to be more competitive, especially in an increasing global market. Globalisation, according to Lucena (2006: 322), has caused trade barriers to fall away and adequate engineering is no longer enough anymore, (Becker, 2006: 262). Engineering has to be such that it can compete internationally (Lucena, 2006: 322).

Taking a step backwards and looking at the complete scope of cost control philosophy one should realise that the very beginning of cost control starts with an estimate of some sort. All the aspects, as mentioned in this chapter, have to some extent an influence on the outcome of the estimate.

Estimating is the key to a successfully conceived, managed and completed project. Estimating is not limited to construction alone, but rather is a function common to a broad spectrum of projects whereby one desires to manage cost and time (Humphreys, 1991: 363). Understanding the accuracy limitations of the estimate and its potential variation is important for the user. Although the final test as to the validity of the estimate can come only when the complete plant has been put into operation, it is possible to make remarkably accurate estimates even before the final process design gives detailed specifications (Peters *et al.*, 2003: 6-7).

The basic essentials of cost estimating (Williams, 1996: 10), as well as the methodology of cost estimating (Brook, 2007: 66; Humphreys, 1991: 367), beg important answers which can lead a project to be a success or failure. For cost control to be effective and to have a good basis for financial reviews, it is very important to have accurate cost estimates. The following chapter will look into the general aspects surrounding cost estimating and will describe the importance of this tool to management.

CHAPTER 3

ESTIMATING IN CONSTRUCTION

1.0 INTRODUCTION

One of the most important tools of control during the course of a project is the cost estimate. All the elements that were discussed in the previous chapter surrounding cost control philosophy will become cost drivers in the cost estimate, whether it is a conceptual estimate or a detailed estimate.

Scope definition or project identification remains one of the most important factors in completing a project within budget and on schedule. Without a proper scope write-up, the estimator will not be able to clearly identify what needs to be included in the estimate and what not. Sharma and Lutchman (2006: EST.16.1) and Brook (2007: 91) suggest that as a project progresses through the various stages of the project cycle, cost estimation occurs as the project scope is “defined, modified and refined”. As the scope becomes clearer the cost estimation process becomes more finite and the range of estimation becomes tighter. It is in the implementation phase that specific scope definition gains greater importance in the cost estimation and scheduling process.

With scope definition comes several added advantages; in other words the clearly defined scope also adds value to the total construction process. Schedule time is brought down to a minimum because uncertainties are eliminated from the start. Rework is either removed from the construction cost, or at least minimised, so as not to cause unnecessary delays and further costs (Ciccarelli, 2004: CDR.11.02). Love and Li (2000: 480) point out that rework does not always constitute work that has to be redone due to poor workmanship. It can also be work that has to be redone due to changes, errors, omissions and quality failures. Abdul-Rathman, Thompson and Whyte (1996: 50) describe rework as the costliest of all mistakes.

When the scope is defined it can be categorised into a work breakdown structure (WBS). A work breakdown structure is a tree-like structure that permits summing of subordinate costs for tasks, materials, etc. into their successively higher “parent” tasks, materials, etc. (Gordon, 2008). For each element of the work breakdown structure, a description of the task to be performed is generated. A work breakdown structure

requires formal change control. This is another reason why a work breakdown structure should be outcome-orientated and not prescriptive of methods.

Scope definition is, as mentioned, the most important factor of estimate accuracy and the work breakdown structure can be useful in improving the estimate even further as well as in assisting in planning the project and auctioning important milestones. The cost estimate can be a useful tool throughout the project. Accuracy of the estimate is therefore important. Humphreys (1991: 368 - 369) stresses that different types of estimates have different levels of accuracy, depending on the purpose of the estimate. There are, however, external factors that may impede the accuracy of the estimate. Should these factors not be properly managed, it might lead to misconceptions later on during the lifespan of the project (Zastrozny, 1974: 16). The estimate purpose is, however, important and will also determine the type of estimate to use.

Uppal (2007: EST.03) refers to estimating as the key to successfully completing any project from conception through detailed engineering, construction and successful start-up. He warns, however, that estimating is an approximation procedure that provides answers with significantly less than 100 percent probability of being correct or even close. As previously mentioned in this chapter Uppal (2007: EST.03) also stresses the importance of scope definition before any estimate can begin.

The engineering construction sector employs different types of estimating models that provide improved answers and are industry specific. Dysert (2004: 9.4) points out that two main types of estimates are used in the engineering field and more specifically in the petrochemical industry. These are “conceptual” and “deterministic” estimating methodologies.

Conceptual estimating methods require a significant effort in data gathering and methods development before estimating preparation even begins. There is a significant effort in historical cost analysis to develop accurate factors and estimating algorithms to support conceptual estimating. Preparing the conceptual estimate itself takes relatively little time (Muscianesi, 2003: 2).

In contrast, a deterministic estimate (detailed estimate) requires much effort during the preparation of the estimate (Kwak & Watson, 2005: 1430). The evaluation and qualification of the project scope can take a significant amount of time (Sharma & Lutchman, 2006: 16.1). Research and application of accurate pricing information and

application of specific estimating judgements to the quantified scope can also add to this time-consuming process.

Different types of estimates should, however, be grouped together to enable the estimator and the rest of the team to announce their purpose of any given type of estimate. In other words the estimator should know, by classifying the estimate, to what degree of accuracy the estimate will have to be and also on what type of information the estimate will be based upon. Estimate classification is such a tool.

Liu and Zhu (2007: 93) and Aslaksen and Vigerust (2007: RISK.02.2) state that formal estimate classifications have been developed to establish a series of “gates” to allow the project team to better manage the estimate process. According to Molenaar (2005: 343), cost estimates should transparently convey the true nature of uncertainty involved in the project at each stage of the process. Estimating procedures must model both the technical and non-technical nature of the challenges in quantifying capital costs early in the project’s life cycle.

The type of estimate determines the clarification thereof, or vice versa. The estimate type is based on the level of detail that the estimator has at his disposal. Depending on the level of available information, the estimator will have to add allowances to the estimate for known and even unknown items, based on experience. Allowances are often included in an estimate to account for the predictable but indefinable costs associated with project scope. A way to include these allowances is by adding a contingency amount to the estimate total (Burroughs & Juntima, 2004: EST.03.1). Such a contingency is required because estimating is not an exact science.

The estimator’s experience has much to do with the allowances that will be added to the estimate (Dysert, 2004: 9.27). The estimate accuracy is therefore dependent (at least to some extent) on the accuracy of the calculation of the allowances. As expected, estimate accuracy tends to improve (i.e. the range of probable values narrows) as the level of project definition improves. Part of improving the estimate accuracy will also be to ensure that the estimate is representative of the complete scope of work. This is mostly done by the estimator in conjunction with management and is known as the estimate review.

The estimate is a prediction of the expected final cost of a proposed project. By its very nature, an estimate is associated with uncertainty and is therefore also associated with

the probability of overrunning or under-running of the predicted cost (Dysert, 2004: 9.27). Leo and Knotowicz (2005: EST.05.1) point out that many companies do not necessarily rely on in-house estimating practices or services. Businesses' estimates are generated by a variety of sources. Some are done by centralised in-house estimating groups, others by groups at a business' international site, or by an array of contractors. Furthermore, estimates are generated in a variety of formats with a great degree of variability with regards to detail and clarity (Sonmez, 2005: EST.07.1).

The need for standardised estimating requirements to put a review process in place has long been realised. By doing so the project team can review the project deliverables and estimated costs before the project is approved for execution. Estimates are checked to make sure that they are complete, accurate and generally ready to use as a project controls baseline.

2.0 REQUIREMENTS FOR AND AIDS TO ESTIMATING

2.1 Scope definition or project identification

Song and AbouRizk (2005: 362) loosely describe project scope as the quantities of construction items within each labour discipline that can be easily measured, such as volume of earth hauled (Son, Mattila & Myers, 2005: 303), concrete poured or the length of pipe installed. This definition is improved upon by Sharma and Lutchman (2006: EST.16.1). Humphreys (1991: 367) also engages in defining scope. These authors' findings are noted in this chapter.

Scope definition or project identification remains one of the most important factors in completing a project within budget and on schedule (Song & AbouRizk, 2005: 361). This is due to the fact that the project scope definition is the reference point for developing estimates and schedules, coordinating teamwork, applying control strategies and evaluating engineering performance. Zastrozny (1974: 3), Love (2002: 138) and Love, Mandal, Smith and Li (2000: 567) stress these points and refer to the importance of scope definition in general. Sharma and Lutchman (2006: EST.16.1) and Alani and Khosrowshahi (2007: 36) refer to the current competitive global environment and point out that the challenge for project leadership is to deliver projects on schedule and within budget. Love and Li (2000: 479) and Sharma and Lutchman (2006: EST.16.1) state that properly planned and phased developmental projects generally

reduce problems associated with project execution and interface connections during expansion of an operating facility or additions to an existing operating facility.

On the other hand, when older facilities are upgraded to facilitate new technologies, or expanded to take advantage of market opportunities, poor planning and a poorly defined work scope can make the task of the project team almost impossible (Coleman, 2006). Moreover, a poorly defined scope and scope changes during project execution can result in significant budget cost overruns, delayed schedules (Hollmann, 2007b: 8), poor work morale, more conflict between procurement contractors (EPC) and owners, and more incidents.

Sharma and Lutchman (2006: EST.16.1) define project scope definition as follows:

> "*Project scope definition is that stage of the project where risks associated with the project are analysed, early designs are formulated, critical decisions are made and the specific project execution approach is defined."*

Humphreys (1991: 367) defines scope of work as follows:

> "*Total work to be accomplished and administrative requirements associated with a contract as described within the contract documents, which may include the general conditions, special conditions, specifications, drawings and addenda."*

Sharma and Lutchman (2006: EST.16.1) and Brook (2007: 91) also suggest that as a project progresses through the various stages of the project cycle, cost estimation occurs as the project scope is "defined, modified and refined." As the scope becomes clearer the cost estimation process becomes more finite and the range of estimation becomes tighter. It is in the implementation phase that specific scope definition takes greater importance in the cost estimation and scheduling process (McCuen, 2008: BIM.01.6). Properly defining the scope of the project and maintaining a strong resistance to what might be considered scope creep (additional work not originally defined in the scope), helps in maintaining schedule delivery within budget. Snedaker (2006) has similar views on the negative impact of scope creep.

Phua and Rowlinson (2004: 48) state that in project management scope definition includes equipment and material to be provided as well as work to be done and is documented by the contract parameters for a project to be completed by a service provider. Sharma and Lutchman (2006: EST.16.1) argue that in its simplified form, scope definition refers to accurately defining the boundaries of the project, defining the resources to complete the work, ensuring all stakeholders are properly informed and have agreed on the task to complete and risks are identified and analysed, and mitigating actions defined. Advantages of scope definition can be summarised as follows:

- With properly defined scopes, there is a higher labour productivity during the implementation or execution of the scoped tasks (Whiteside, 2006: EST.08.3).
- Scope definition allows for clearly defined and planned-for interface requirement thereby facilitating easier execution.
- A properly defined scope generates cost savings from material management, interface management and a reduction of production losses for tie-ins on live facilities (Anonymous, 2008j and McCuen, 2008: BIM.01.6).
- Properly conducted scope definition with stakeholder involvement results in reduced instances of overlooked obstacles during the execution stage (Al-Duaij, Awida & Kollarayam, 2007: 24).
- There are fewer incidents and accidents during the execution stage of the project. There exists ample proof of poor planning leading to incidents in construction. Rashbaum, (2008a: New York Times, 24 September 2008), Rashbaum, (2008b: New York Times, 19 September 2008), Rashbaum, (2008c: New York Times, 16 September 2008), O'Connor, (2008: New York Times, 12 September 2008) and Lee, (2008: New York Times, 12 September 2008) all elaborate on incidents on construction sites in recent history that occurred only in New York.
- Conflicts are reduced and significantly less time is spent amongst stakeholders resolving discrepancies.

Scope definition is arguably the single most important cost driver that influences the ability to forecast project cost (Sharma & Lutchman, 2006: EST.16.1). When the scope is being defined, the aim is to better the engineering, cost forecasting in work

packages and management of change, quality and timing of information. Sharma and Lutchman (2006: EST.16.1) state that project scope evolves across the various stages of the project cycle. During the implementation and control phase of the project cycle, the level of scope definition is most useful in assisting the project team in managing both cost and schedule. Figure 3.1 illustrates the project cycle.

The scope statement is the document basis for making project decisions. This is important to have a common understanding of a project amongst the team members. The scope statement can be revised or refined as the project evolves (Song & AbouRizk, 2005: 362). The scope write-up generally comprises or refers to the following components:

- Project justification: The project justification encapsulates the business need for undertaking the project while providing a basis for future trade-offs.
- Project product: This section summarises the product description which is a compilation of characteristics of product or service to be created upon completion of the project.
- Project deliverables: Project deliverables refer to a list of finished products to be delivered by the service provider (contractor) upon full implementation and execution of the project.
- Project objectives: The project objectives define quantifiable criteria that must be met for the project to be considered successfully completed.

Table 3.1 shows stakeholders classified into two categories. Parties involved in scope definition can either be internally or externally involved. Involvement of both groups is essential to effective scope definition. Interfacing between these parties is essential – especially when designing a green field project. The uninformed observer might think that it will be unnecessary to involve all parties stated in Table 3.1. Concerns are raised when all parties are involved that the project will not be finished in time and that it might lead to cost loading.

Sharma and Lutchman (2006: EST.16.3) advise that when all parties are included in the project team (particularly during the project definition), an agreed-to project execution plan is developed that should minimise the potential for changes being introduced during detailed engineering and construction. Further advantages include continuation of the team raising productivity, reduction of potential scope changes and

associated negative externalities during the implementation and control stage of the cycle (Berg & Hinze, 2005: 830).

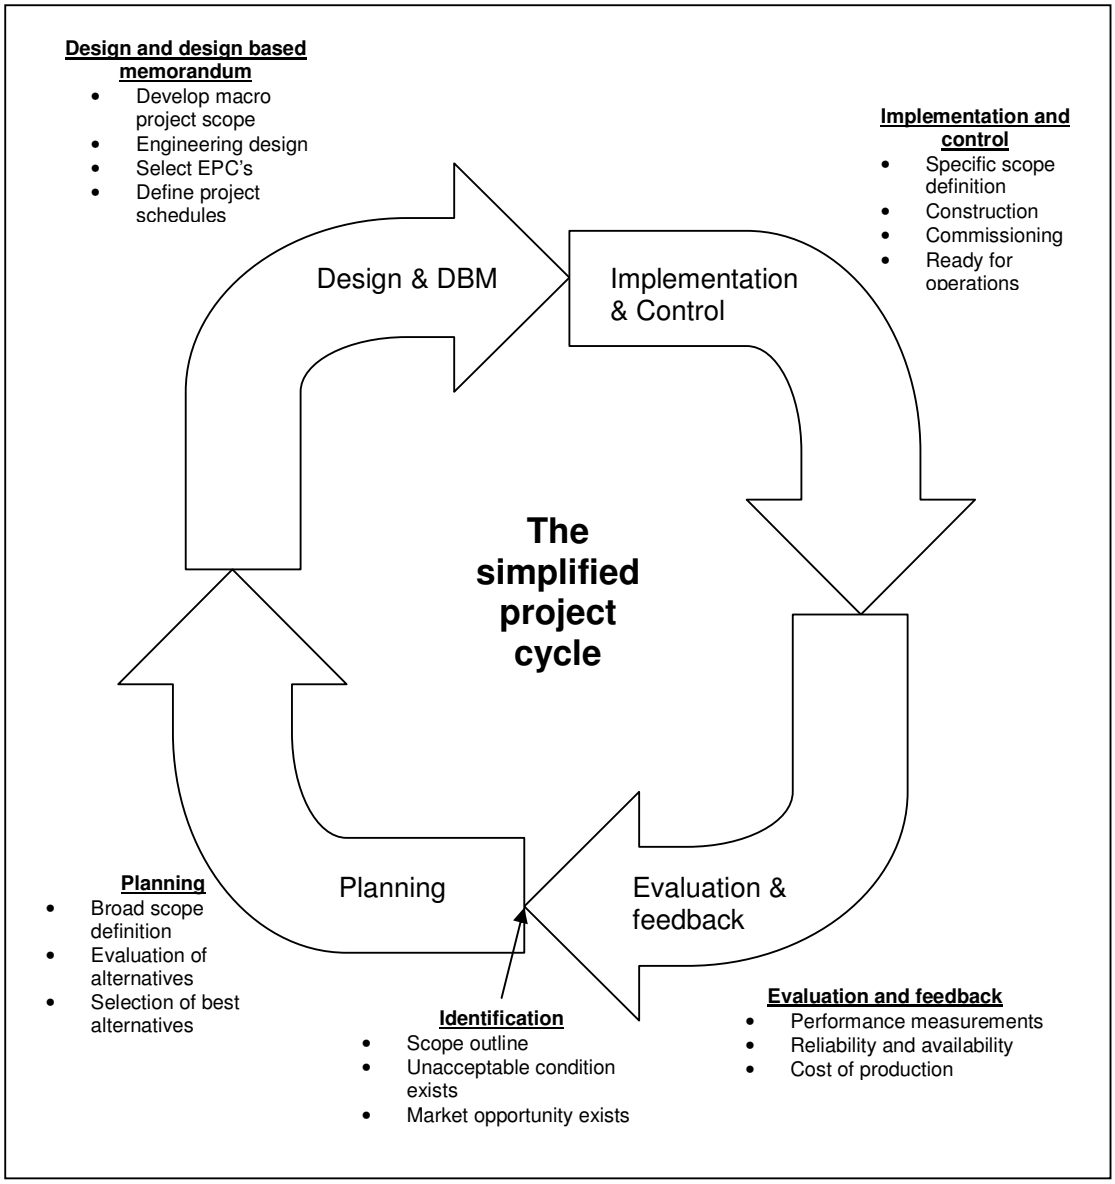

Figure 3.1: The simplified project cycle

Source: Sharma and Lutchman, 2006: EST.16.2

Ultimately, a clearly defined scope with joint internal and external stakeholder involvement, aligned interpretation of scope and a common vision among all stakeholders creates opportunities for project implementation and execution that minimises stakeholder value and avoids costly budget overruns and project delays (Shi, Cheung & Arditi, 2001: 63).

Internal to the organisation	External to the organisation
Leaders	
End users	Engineering and procurement contractors
Support services (maintenance and accounting, etc.)	Suppliers
Planner and business analysts	Consumers
Project management team	Special interest and lobby groups
Engineering team and disciplines	Regulatory bodies
Loss management and safety advisors	

Table 3.1: Classification of stakeholders

Source: Sharma and Lutchman, 2006: EST.16.3

Project scope management should also be considered as key in controlling changes on the project. Song and AbouRizk (2005: 360) indicate that scope management is critical to the success of the project. They summarise the scope management process in the following key words: involving, initiation, scope planning, scope definition, scope verification, and scope change control.

2.2 Scope factors contributing to cost overruns and delayed schedules

Poor scope definition has led to significant cost overruns on many projects in the past (Hanvey, 2008; Anonymous, 2008i). While in no way exhaustive, common causes identified where scope definition is involved as precursors for cost overruns and schedule delays include the following:

- Grey areas up to interpretation by service providers (contractors).
- Incomplete scope definition of overlooked elements of the scope.
- The need for rework.
- Concurrent work and risk management.
- Poor interface definition and preparation.
- Scope expansion and scope changes.

2.2.1 Grey areas up to interpretation by service providers

Generally, activities that are small in value and repetitive in nature lend themselves easily to poor scope definition (Bowen, Pearl, Cattell, Hunter & Kelly, 2007: 59). Often the project team decides that it is not worth incurring engineering hours on defining the scope of such small activities, leaving it up to interpretation by the service providers. Sharma and Lutchman (2006: EST.16.4) explain this phenomena by means of a project to increase oil and gas operations which went wrong due to poor scope definition. The running of electrical cables was limited to generic wording such as “run cables from substation to pump motors in tray baskets”. Lack of details surrounding the cable route and cable tray usage left scope interpretation open to the contractor to maximise returns from this project. The unintended consequence of such omission is a loading of small cost to the project which over time, if undetected, can result in significant cost overruns.

2.2.2 Incomplete scope definition of overlooked elements of the scope

Incidents of incomplete scope definition are very common when end users are not consulted or involved in defining the scope of the project. End user involvement should begin very early in the project cycle. End users continually identify opportunities for upgrades and repairs in an existing facility that can be easily executed during project expansion work (Vianna & Teles, 2008: EST.11.1).

Another factor that can fall within this category occurs when owners attempt to fast track a project. Fast tracking a project can save a great deal of time and money when implemented judiciously (Sappe, 2007: 21). On the other hand, it can be akin to a blank cheque to contractors when the scope is not properly defined; which normally is the case in fast track contracting. A typical example is when drawings, which have not undergone all reviews, are provided to vendors for pricing purposes. This approach can expedite the procurement process; however, changes during the review process almost always lead to changes in scope. This will invariably lead to cost increases during the construction phase.

2.2.3 The need for rework

Love and Smith (2003: 147-148) define rework as:

> *"…the process by which an item is made to conform to the original requirement by completion or correction."*

They also comment on the definition of rework as provided by The Australian Construction Industry Development Agency (CIDA). CIDA define rework as:

> *"…doing something at least one extra time due to non-conformance to requirements."*

Ashford (1992: 12) also includes repairs as a form of rework. He defines a repair as follows:

> *"…the process of restoring a nonconforming characteristic to an acceptable condition even though the item may still not conform to the original requirement."*

Love and Li (2000: 480) point out that rework does not always constitute work that has to be redone due to poor workmanship. It can also be work that has to be redone due to changes, errors, omissions and quality failures. The Building Research Establishment (BRE) in the United Kingdom found that 50% of all errors in construction had their origin in the design stage and 40% in the construction stage (Love & Smith, 2003: 147-148). The BRE concluded that the biggest culprits in rework in design were the lack of coordination of design and unclear or missing documentation. Love and Smith (2003: 148) suggest that, based on research conducted by Cnudde, a rework factor of up to 10% of the contract value can be experienced on projects with poor quality control.

Love and Smith (2003: 148) reported that a major Australian construction company had experienced rework costs of 5% of the contract value in one project that were attributable to poor documentation by the design team; furthermore, the subcontractor in question experienced a 31% cost increase. Love and Smith (2003: 149) also proved through their research that the cost to rectify a poor quality product or service can be more than eight times the original cost. Costs due to rework in a specific sector of the Swedish construction industry ranged from 2,2% to 9,0% of the contract value. Of this 50% originated from site and 32% was due to the client or design inconsistencies. Love, Smith and Li (1999: 638) point out that in the Australian context "… it is suggested that most organisations have learnt to accept it as part of their operations,

inasmuch as they have not realised its true extent or its influence on their own and a project's performance."

Anonymous (2006c) describes rework as the costliest of all field mistakes. Love and Sohall (2003: 330) comment on the capturing of rework costs. When scope is poorly defined, it is not uncommon for the completed product to be unable to fulfil the goal it was initially intended for. In such cases, rework is required after the final product is tested and found unsuitable for addressing the concerns or opportunities initially identified. Love (2002: 139) states that the outcome of rework is always unintended expenditures and costly delays. Rework can also result from damage incurred after the project is completed and before it has been energised (Love *et al.,* 2000: 568). In most cases this form of rework results in minor costs.

Sharma and Lutchman (2006: EST.16.5) illustrate, by means of an example, a typical poor engineering design that resulted in rework. A sub-project of electronic data collection in an industrial environment by means of hand held computers resulted in rework. The idea to use hand held computers was not communicated in the scope write-up before the project started. The project team failed to consider the physical size of these computers and the impact it would have on the operators during the conduct of their duties, such as climbing cat ladders at elevated heights at -25°C while wearing protective gloves. Poor data collection resulted in a costly hardware change to ensure that the correct data was collected.

Efforts to reduce failures in construction projects by studying their causes have led to a meaningful reduction in occurrences (Love & Josephson, 2004: 70). The same authors point out that the main causes of rework in construction can be attributed to human error. Love & Josephson (2004: 70) state that a plethora of human errors have been reported in the popular press. The Swedish newspaper, *Göteborgs-Posten*, for example reported on the error that resulted in a section of the Chalmers Tunnel not following the correct profile. The error occurred in the data input phase of the design of the tunnel. Love and Josephson (2004: 70) suggest that errors can essentially be avoided by eliminating the root causes using techniques embedded in the philosophy of total quality management, e.g. root cause analysis and failure mode effect analysis.

Figure 3.2 illustrates the chain of events from the cause of the error to the corrective measure. The causes of errors are often difficult to determine because there can be several apparent causes for the same erroneous action. Identifying the root cause of

an error and altering this cause will have the effect that the recurrence of the error can be prevented. Figure 3.3 demonstrates the tracing of apparent and root causes of errors.

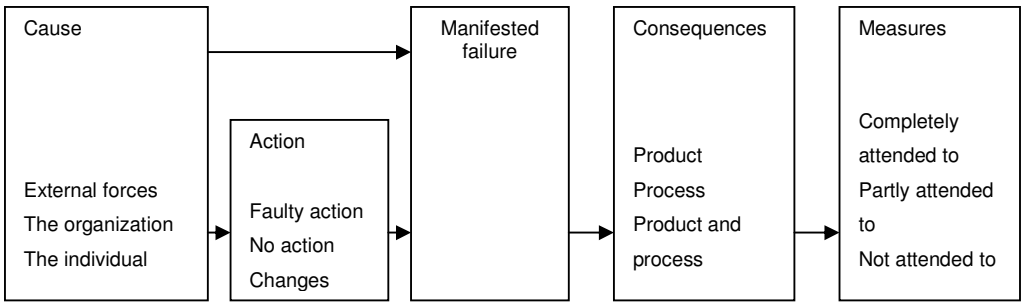

Figure 3.2: Chain of events model

Source: Love and Josephson, 2004: 71

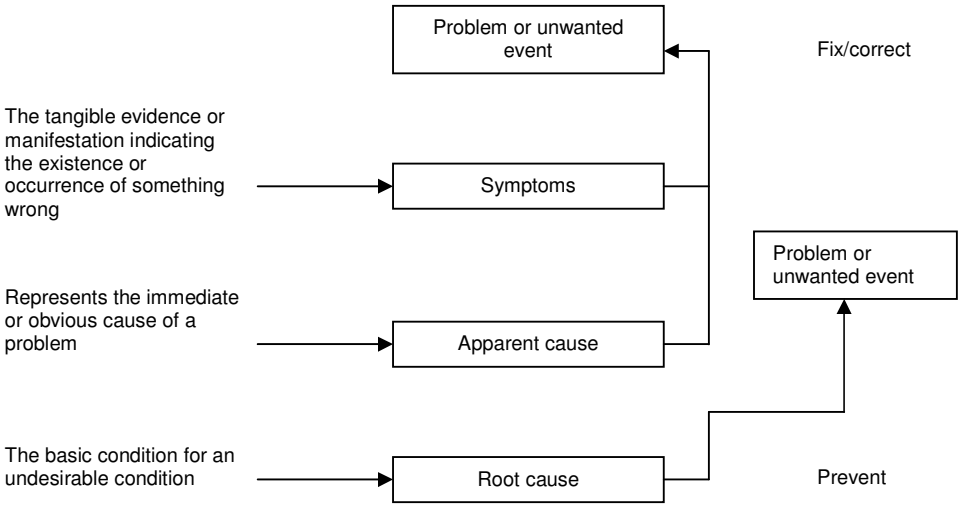

Figure 3.3: Apparent and root causes of errors

Source: Love and Josephson, 2004: 71

Love and Edwards (2004: 261) indicate by means of Figure 3.4 the determinants of rework.

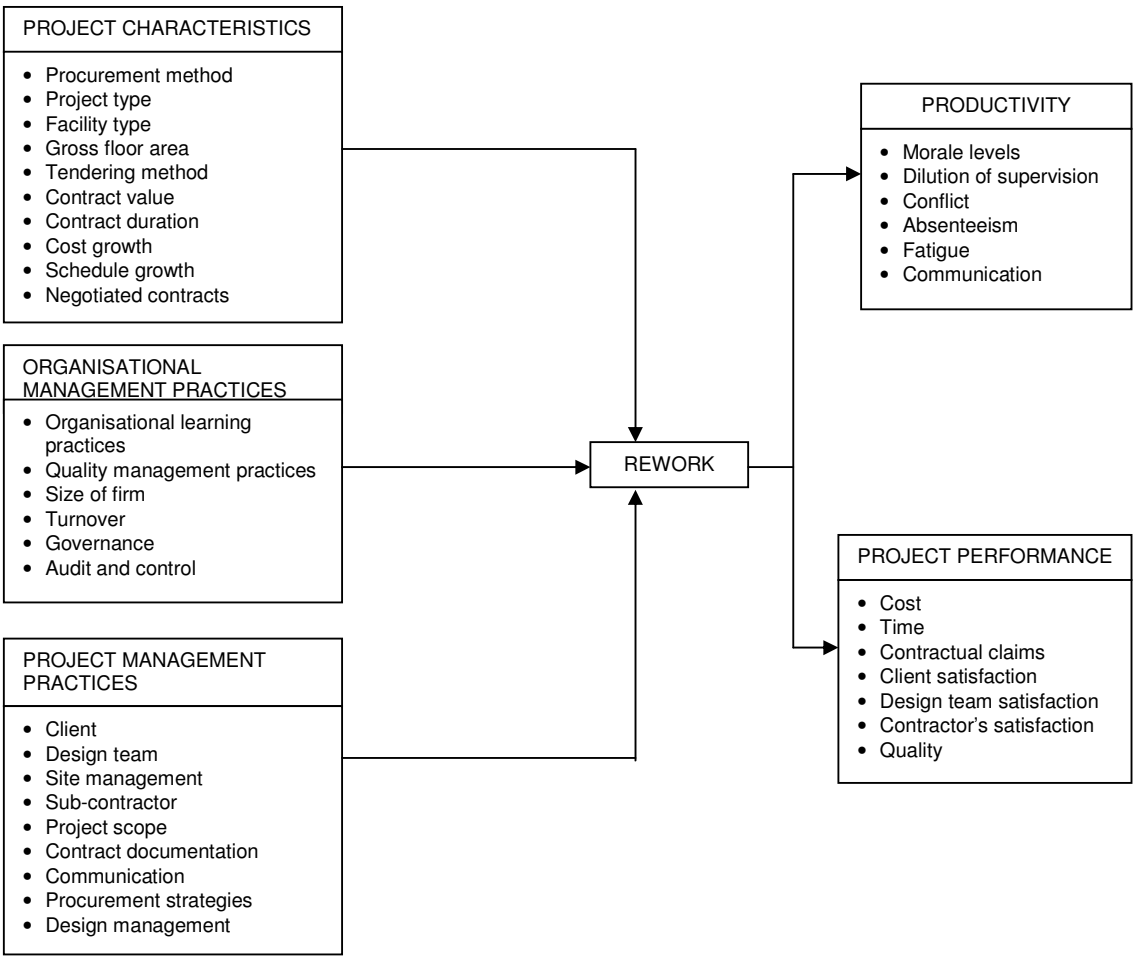

Figure 3.4: Conceptual model of rework determinants

Source: Love and Edwards, 2004: 261

2.2.4 Concurrent work and risk management

Snedaker (2006) points out that changes to the scope can either be managed or unmanaged. The amount of unplanned concurrent work to be undertaken during the implementation stage, not included in the scope definition, holds significant implications for the project cost and schedule delivery. This is particularly important for expansion of live facilities where continuous operation is occurring on the same site on which construction activities are taking place. Unplanned and unmitigated risks from overhead lifting, for instance, may result in increasing cost and schedule delays (Bradshaw & Gruber, 2007: PM.09.4).

Aslaksen and Vigerust (2007: RISK.02.2) researched the Ormen Lange Project in Sweden. They found that there are six steps in the risk management process, which can be described as follows:

- Preparation for risk management
- Identify risks
- Evaluate risks
- Develop action plans
- Respond to risks
- Risk communication

Figure 3.5 illustrates the process of risk management. Aslaksen and Vigerust (2007: RISK.02.2) elaborate on the mitigation of risk in construction and describe the procedure used in the Ormen Lange Project. A risk register is maintained. When performing cost risk analysis (CRA) or schedule risk analysis (SRA), the risk register is evaluated according to each area. Relevant risks from the register are either used as a basis for maximum or minimum values or incorporated as separate events/activities in the analysis.

Lofton and Coppo (2007: RISK.05.1) stated that proper risk analysis should identify the following:

- Cost risk: An additional value to a quantity or cost uncertainty or an event which will occur with a certain probability, and which will have a certain cost and/or schedule impact if it occurs.
- Schedule risk: An activity with uncertainty. An additional cost or time to oblige for the mitigating actions has to be agreed on.

More information will follow in this study regarding risk management in construction.

2.2.5 Poor interface definition and preparation

The scope of work should be clearly defined especially where there are interfaces between different disciplines or different systems (Anonymous, 2008i). Scope definition should also address the risks and mitigation plans for live and new systems during interface management and preparation. A typical example of interface management

between disciplines occurs when defining boundaries for instrumentation and communication cables (Motlong, 2008: Financial Mail – 12 September) that reside within the scope definition of electrical work. Sharma and Lutchman (2006: EST.16.5) refer to another example of poor scope planning whereby a cogeneration facility was to be integrated with a commercial steady state oil and gas operation, which resulted in several unplanned shut downs and unnecessary costs.

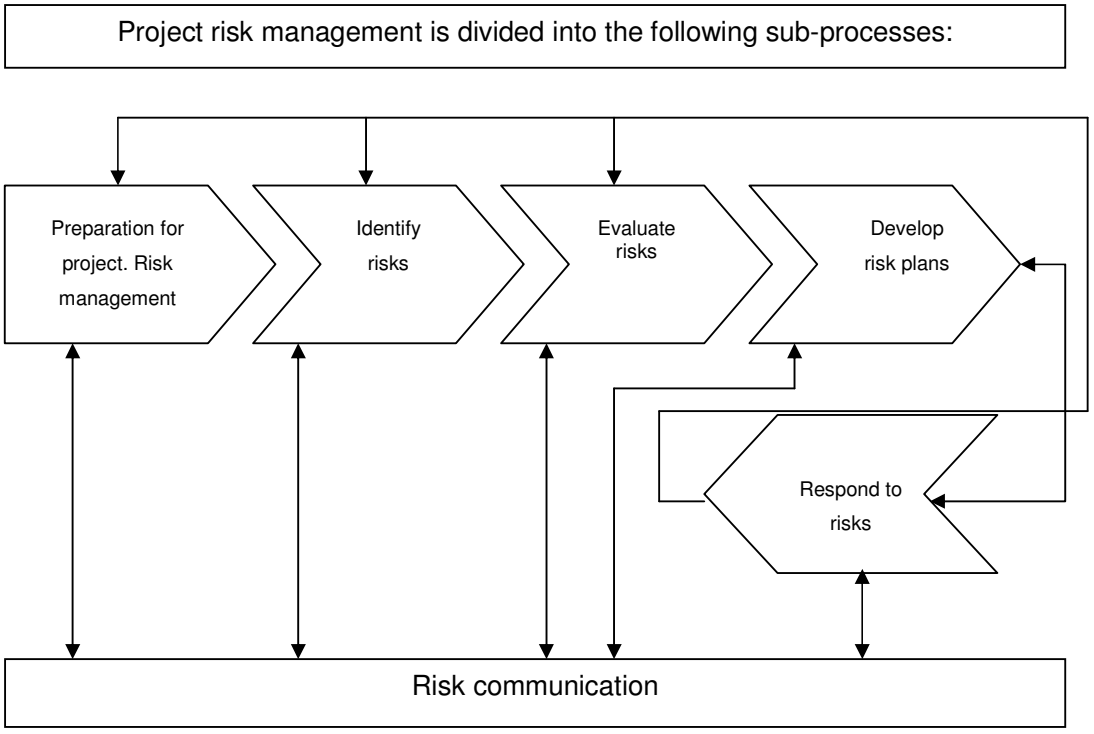

Figure 3.5 Risk management process
Source: Aslaksen and Vigerust, 2007: RISK.02.2

2.2.6 Scope expansion and scope changes

Anonymous (2008k) comments that major scope expansions or changes do impact the project because they are normally identified by the project controls team and are filtered out for proper sequencing and actions. Small scope changes and expansions are often referred to as scope creep. These changes are within the project team's capabilities to execute, but can result in a significant cost increase (Al-Duaij, Awida & Kollarayam, 2007: 23).

Barlow (2006:12) reports (as mentioned in Chapter 2) that the cost implications of material specification change increase dramatically as the project progresses. Early changes are therefore much cheaper. Sullivan (2008) expands this philosophy and illustrates this chain of thinking in total scope change. The earlier a change to the scope is made in the life of the project, the less effect it will have on the schedule. Figure 3.6 sketches a graphic explanation of this statement.

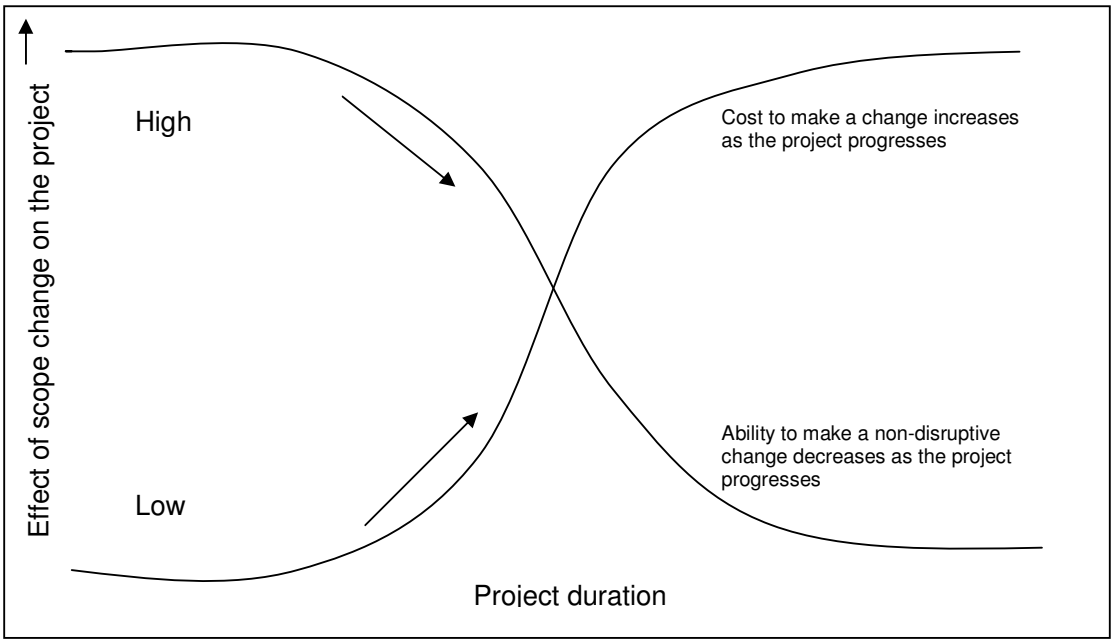

Figure 3.6 Effect of scope change on the project schedule
Source: Sullivan, 2008

Sullivan (2008) proposes creative strategies to deal with change without incurring unnecessary delays and additional costs. Polaski and Horman (2005: 1276) point out that these strategies are similar to value engineering whereby the parties involved scrutinise the design and look for items that can be deleted or modified to make the project more cost-effective (Shengping & Tiong, 2004: INT.08.1). Figure 3.7 illustrates this process.

3.0 WORK BREAKDOWN STRUCTURE

Phillips (2005) probably offers the best definition of what a work breakdown structure is. He states:

"A work breakdown structure (WBS) is a deliverables-orientated decomposition of the project. It is not the activities needed to create the project deliverables; it is the outcome that the activities create."

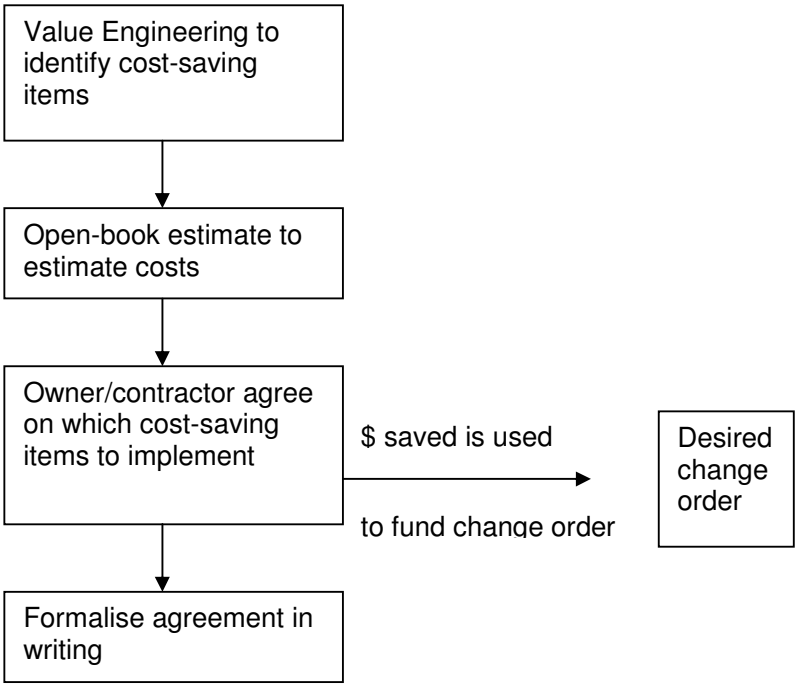

Figure 3.7 Basic process of creative thinking in change order management

Source: Sullivan, 2008

A work breakdown structure is a tree-like structure that permits summing of subordinate costs for tasks, materials, etc. into their successively higher "parent" tasks, materials, etc. (Gordon, 2008). For each element of the work breakdown structure, a description of the task to be performed is generated. A work breakdown structure is organised around the primary products of the project, (Biffi, 2008). As previously stated this means that the work breakdown structure is organised around the planned outcomes rather than planned actions (Kauffmann, Keating & Considine, 2002: 13).

These tasks or "work packages" are described by Humphreys (1991: 471) as follows:

"A work package is a well-defined scope of work that terminates in a deliverable product(s) or completion of a service. Each package may vary in size, but each must be a measurable and controllable unit of work to be performed."

3.1 History of the work breakdown structure

The concept of the work breakdown structure developed with the Program Evaluation and Review Technique (PERT) in the United States Department of Defence (Anonymous, 2008l). PERT was introduced in the United States of America's Navy in 1957 to support the development of the Polaris missile program. By June 1962 the United States of America's Department of Defence, NASA and the aerospace industry published a guidance document for the PERT cost system which included an extensive description of the work breakdown approach. In 1968 the Department of Defence issued Work Breakdown Structures for Defence Material Items (MIL-STD-881), a military standard mandating the use of work breakdown structures across the Department of Defence. This document has been revised several times, most recently in 2005.

In 1987 the Project Management Institute (PMI) documented the expansion of these techniques across non-defence organisations (Anonymous, 2008m). The Project Management Body of Knowledge (PMBOK) Guide provides an overview of the WBS concept, while the Practice Standard for Work Breakdown Structures is comparable to the Department of Defence Handbook, but is intended for more general use.

3.2 Planned outcomes, not planned actions

Billows (2008a) indicates that the work breakdown structure should include 100% of the work defined by the project scope and should capture all deliverables – internal, external, interim – in terms of the work to be completed, including project management. This "rule" is referred to as the "100% rule" and is one of the most important principles in guiding the development, decomposition and evaluation of the work breakdown structure (Anonymous, 2008l). The rule applies at all levels within the hierarchy: the sum of the work at "child" level must equal 100% of the work at "parent" level and the work breakdown structure should not include any work that falls outside the actual scope of the project.

Should the work breakdown structure designer attempt to capture any action-orientated details, he will likely include either too many actions or too few (Billows, 2008b). This will have the effect that the complete "parent" scope will not be addressed. Figure 3.8 shows an example of a typical simplified work breakdown structure for an aircraft system.

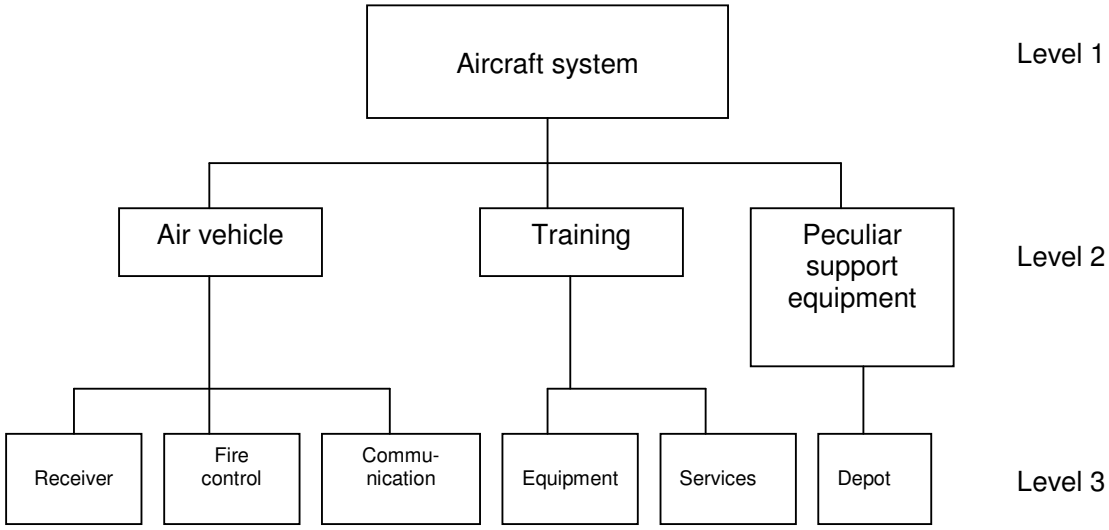

Figure 3.8 Work breakdown structure of an aircraft system

Source: Anonymous, 2008l

3.3 Common pitfalls and misconceptions

Anonymous (2008l) notes that a work breakdown structure is not an exhaustive list of work. Instead it is a comprehensive classification of project scope. It is also not a project plan or a project schedule and it is not a chronological listing. According to Mathis (2008) and Gordon (2008), it is considered to be poor practice to construct a project schedule before designing a proper work breakdown structure. The work breakdown structure is not an organisational hierarchy and it should not shadow the organisational chart.

A work breakdown structure requires formal change control. This is another reason why a work breakdown structure should be outcome-orientated and not prescriptive of methods (Anonymous, 2008l). Methods change frequently, but changes in planned outcomes require a higher degree of formality. If outcomes and actions are blended, changes control may be too rigid for actions and too informal for outcomes (Anonymous, 2008n).

4.0 INFLUENCES ON ESTIMATE ACCURACY

Humphreys (1991: 368 - 369) emphasises that different types of estimates have different levels of accuracy; depending on the purpose of the estimate. There are, however, external factors that may impede on the accuracy of the estimate (Prince,

2002: 10). Should these factors not be properly managed, it might lead to misconceptions later on during the lifespan of the project (Zastrozny, 1974: 16).

4.1 Economic climate change in construction

The economic climate in countries worldwide is ever changing. Different factors effect the economic situation. The construction industry is also affected by the greater local economics and the international economic scene. Ample examples exist of the current international occurrences that have significant effects on the world economy. Moola (2008: Financial Mail – 15 August) describes the economic growth in China. Zou and Wong (2008: 279) also depict the current economic situation in China. Klopper (2008: Radio broadcast 21 November) states that America's prime lending rate is 0,01%, which results in a 10 cent return per annum for every $100 lent. Staff reporter (2008: Accessed 21 November), Buffet, (2008: Accessed 21 November), Schoen, (2008: Accessed 21 November) and Austin (2008: Accessed 21 November) all comment on the current American economy and how it influences the world economy. Benjamin (2008: Accessed 21 November) and Laubscher (2008: Accessed 21 November) elaborate on the current South African economy, while Anonymous (2008u: Accessed 21 November) reports on the possibilities of normalising the Zimbabwean economy.

Anonymous (2008o: 6) describes how the recent recession in the United States and the stagnation in Japan caused major difficulties for construction companies worldwide. Vinci remained the world's top contractor for 2007 and French company Bouygues remained in second place, but the rest of the competition was completely reshuffled. Hazelton (2008: 16) reports on the European situation and states that the construction industry will be dragged into a mild recession for the next two years because of the world economic situation.

Rameezdeen and Ramachandra (2008: 499) draw parallels between a country's economy and its construction sector. In fact, the industry first affected by any country's economy is the construction industry. Rameezdeen and Ramachandra (2008: 499 - 500) researched the current situation in Sri-Lanka where they found that the effects of economic change had almost immediate impact on the local construction industry. Construction plays an important role in economic development. Wong, Chiang and Ng (2008: 824) describe, by means of empirical research, the complexity and similarities between the Hong Kong economy and its construction industry. Hua (2008: 485) indicates the complexity of the construction industry and how the economy can

influence the industry, while Jha and Devaya (2008: 337) report on the small percentage of the international construction market that India manages, but how even this small percentage (0,05% of $3 to 4 trillion) has a positive effect on the Indian economy.

According to Johnson (2007: 30), the consumption and availability of resources such as fuel and electricity also play a role in the economic climate of a country and ultimately on construction costs. Jacobson and McLay (2006: 308) report on the effect of fuel consumption on the economy. Parry (2008: Financial Mail. 29 August 2008) also comments on the price fluctuations in crude oil and how this impact on the economy. Lünsche (2004: Financial Mail. 10 December 2004) shows the possible effects of electricity supply on the economy. Anonymous (2008q: 10) reflects the effects of the price of steel on the different industries in America. The economy in the United Kingdom has influenced the construction business to such an extent that brick manufacturing is at its lowest level in 60 years (Anonymous, 2008t: 5).

The overall state of the economy and ultimately the construction industry is influenced by the above-mentioned factors, which also have an effect on the lending market (Strugnell, 2008: 48) and credit control (Beech, 2006: 18). Anonymous (nd: 30) discusses the effect of the lending market and credit control on Latin American countries. Galf and Monacelli (2008: 117) indicate the advantages of optimum monetary and fiscal policy and how such a standard economic principle can direct the economy.

4.2 Contracting and type of contract used

Contracting is a primary method that both owners and contractors use to allocate identified risks associated with a project (Lucas, 2007: OWN.05.1). In the current global construction market, the risks associated with long term major capital projects are high because of various supply and demand factors. This requires both the owner and the contractor to be innovative in their contracting strategies in order to mitigate their perceived risks.

The different types of contracts used on a project have a significant impact on the complexity of providing accurate and consistent information. The cost analyst must recognise the contract types and be able to implement the appropriate forecasting techniques (Lucas, 2007: OWN.05.1). Although not the purpose of this study, it is

necessary for the cost estimator to understand that different contract types have different views on specific issues. Claims, for example, are treated differently depending on the contract in question (Hassanein & El Nemr, 2007: INT.04.1).

Berends (2006: 36) indicates that the difference between an Engineering, Procurement and Construct (EPC) contract and a For-and-on-behalf type contract or Project Management Contract (PMC) lies to a large extent in the mitigated risks. Yongqiang, Fei and Libo (2004: Paper presented at The 4th World Congress of ICEC) comment on cost associated with PMC contracts. A contracting firm tendering on an EPC contract will have to price according to the risks associated with the scope of work (Yonezawa, 2005: CSC.18.1). The two main differences between the different contract types are the distribution and sharing of risks and the remuneration of the contracting company (Berends, 2006: 36). The cost-plus-fee type contract poses perhaps the least risk for the contractor, which will positively influence the tenderer's rates (Rossetti & McKeeman, 2008: 6).

Creech (2006: OWN.1.02) points out that different contract types have different requirements when it comes to administration and related issues such as mediation, arbitration, etc. Zuckerman (2007: 43) describes the costs involved with these legal processes. Broome (1999: 6-7) sheds light on the constant drive to simplify contract documentation with a resulted reduction in costs. The basic concept for increasing or decreasing costs on a project is to alter the risks associated with the project accordingly (Ribeiro, 1996: 55). Swart (2004: Paper presented at The 4th World Congress of ICEC) comments on the value of good administration for any party to a contract.

4.3 Foreign currency fluctuations

The international construction business is sensitive to world events and it entails political, financial, cultural, and legal risks (Belcher, 2004: 2 and Cheung, Suen & Lam, 2002: 411). Understanding the opportunities and threats associated with international markets and assessing a company's preparedness for international ventures are crucial to the growth and sometimes the survival of construction companies (Gunham & Arditi, 2005: 273). Han and Diekmann (2001: 300) indicate that globalisation of construction markets allows for local construction companies to compete internationally. The threats and opportunities of target countries should be understood (Hastak & Shaked, 2000: 59). Gunhan and Arditi (2005: 275 - 280) list some of the

pitfalls in international construction. They are project management capability, international network, financial strength, foreign competitors, cultural differences, and bribery and corruption in the host country. Chan, Tam and Cheung (2005: 111) report on similar findings in the Hong Kong construction sector.

Possibly the latest project to fall victim to the added cost to the budget due to foreign currency fluctuations in South Africa is the Gautrain project (Venter, 2008: Accessed 03 December 2008). Venter comments that the project manager of this project, Jack van der Merwe, mentioned that approximately 20% of the total project value of R25 billion will be spent overseas and will therefore be subjected to foreign currency fluctuations.

Any construction firm venturing overseas will have to deal with foreign currency fluctuations and will have to allow for this as a risk item in the tendering process. The world economy dictates the markets and the influences on foreign currencies (Minahan, 2007: 24). This sensitive nature of foreign currencies, for instance, had BHP Billiton applying crisis management to some extent in 2003 (Anonymous, 2003a: The Sydney Morning Herald. 24 February). Anonymous (2003b: The Sydney Morning Herald. 24 February) reiterates these findings. Chadee and Crow (1997: 41) and Burnside, Eichenbaum and Rebelo (1999: Paper presented at conference held at The World Bank. 03 August) also comment on the influences of foreign currency fluctuations. Kawai and Akiyama (2000: Seminar - Kuala Lumpur. 30 May) report on the currency crisis for exchange rate arrangements in emerging East Asia. Anonymous (2008v: Accessed 03 December) and Henock (2008: Accessed 03 December) describe the influence of foreign currency fluctuations on the broad economy.

4.4 Weather conditions

Inclement weather causes disruptions on construction sites the world over on a daily basis. The importance of weather on the costing of a project has long been realised. Cohen (1990: New York Times 19 August) mentions an increasing number of private companies engaging in weather forecasts/databases to assist them in improving their costing. Although estimators allow for unfavourable weather conditions during construction, it is the unforeseen or abnormal conditions for which there has not been allowed for that will cause financial losses (Doyon & Werick, 2008: Accessed 9 June). Too much rain, snow, cold and heat can cause construction to be either impractical or unsafe. Nogueira and Paixão (2007: 545) comment on health risks due to heat when performing construction work. De Villers (1986: 1) reports that already in 1986 the

annual financial losses due to inclement weather in the United States amounted to between $3 and $10 billion per annum. Palutikof (2006: 66) refers to the decline in activities during the drought summers of 1975 – 76 and the severe winters of 1962 – 63 in Great Britain.

Unfavourable weather conditions can cause rework which will be for the construction company's account. Extreme cold can, for example, freeze concrete influencing its strength Afrisam (2008: Technical guide to the use of rapid strength cement). Ekanayake and Ofori (2000: Paper presented – Pretoria; 23 – 25 August) and Faurie, J. (2008: Martin Creamer's Engineering News – 07 November) also refer to weather influences on construction materials.

4.5 Labour availability, productivity and political influences

The influence of labour on the cost of a project was discussed in Chapter 2. Townssend and Charles (2008: 67 – 68) report that from the earliest times to the Industrial Revolution the craft of skilled trade was the basic unit, the elementary cell of the labour process. In each craft the worker was presumed to be the master of a body of traditional knowledge, and methods and procedures were left to his or her discretion. In each such worker repose the accumulated knowledge of materials and processes by which production was accomplished in the craft. The potter, tanner, smith, weaver, carpenter, baker, miller, glassmaker, cobbler, etc., each representing a branch of the social division of labour, was a repository of human technique for the labour processes of that branch (Jackson & Rogers, 2007: 895).

Townssend and Charles (2008: 68) make the statement; "…there is arguably enough a much less significant level of skill utilisation in many contemporary work stations." Esposto (2008: 101) describes skill as the ability that comes from knowledge, practice, aptitude, etc., to do something well. Esposto (2008: 103) proposes several methods for measuring skill and also comments on the steady decline of skill in the workplace. Hall and Leeson (2007: 658) indicate that there exists a trade-off between labour standards and income and that some first world countries made this trade-off years ago and are today reaping the benefits. They add that many sub-Saharan countries will only reach this point between 100 and 300 years from now.

Hall and Leeson (2007: 658 – 659) illustrate this point by means of an example. Romania's government structure is in many ways based on those in other modern

countries. Their tax system is, for example, based on that of the United States. Their gross domestic product per capita, however, is (at the time of this research) $3,167. The United States already reached this point in 1887. Developmentally, the United States' equivalent of Romania is 120 years ago. Hall and Leeson (2007: 659) point out that this is largely due to the state of skilled labour in these two countries. O'Mahony, Robinson and Vecchi (2008: 1435) state that the skills premium has increased because the demand for skills by modern technology has risen even faster than the supply. According to Addison, Bellmann, Schank, and Teixeira (2008: 115), the situation in Germany is no different. For several decades now the demand for unskilled labour has declined and that of skilled labour has risen.

It is inevitable that the decline of skilled labour will have an effect on wage rates. Borowicz (2007: 19) outlines the effect of wage rates on construction cost. Anonymous, (2006a: Business Week - 27 March) refers to the sudden increase in construction cost at the time in China due to unforeseen increased construction labour wages. Blandy (2006: 2) seconds the reform of the Australian labour market and states that the increasing involvement of unions and increased wages necessitate this step. Tan, Lester and Richardson (2008: 80) concur with these findings. Campbell (2008: 1389) mentions a general international trend in higher-than-usual wage increases and abnormalities due to an increased demand. Lechthaler and Snower (2008: 1224) add training as a prerequisite for improved skills in the labour market and demonstrate the effect of training. Training will result in an initial increase in wages, but will have added benefits at a later stage (Matsaganis, 2007: 540). Together with training, factors such as income protection (pension) and union involvement (Matsaganis, 2007: 537), will have an effect on wage rates, depending where construction takes place.

Saville (2010: Mail & Guardian – 10 September) points out that skilled labour availability in South Africa is declining. Würth (2006: 97) and Saville (2010: Mail & Guardian – 10 September) both indicated that it is crucial for South Africa to increase its productivity to improve economic growth. Letsoalo (2010: Mail & Guardian – 21 May), Steenkamp (2010: Die Burger – 19 May) and Barnard (2010: Die Burger – 11 May) all point out negative effects of recent labour strikes in South Africa. Hancock (2010: Engineering News – 8 October) and Anonymous (2010b: Mail & Guardian – 20 April) refer to the effects of political interference on the construction of nuclear power plants which in turn has a long term effect on the availability of power and ultimately on the South African economy. Poor economic conditions in neighbouring countries also

cause labour migration which in turn puts strain on the South African economy (Dagut, 2006: 262).

The basic principles surrounding productivity were discussed in Chapter 2. The measure of productivity is a complex process. Whiteside (2006: EST.08.1) states that it will be wrong to assume that productivity is measured uniformly and that all productivity values have the same basis. Quiggin (2006: 18) reports on the effect of productivity on the Australian economy. Picard and Hutcheson (2008: PM.11.1) comment on the growing need to increase productivity in the American construction industry. Refer to Figure 3.9. According to Motwani, Kumar and Novakoski (1995: 18), it is relatively easy to establish the quantity of work to be performed and the cost per hour for labour to perform that work. However, it is the identification and the evaluation of the critical factors which influence productivity that provide a challenge (Enshassi, Mohamed, Mayer & Abed, 2007: 358). Errors in productivity estimation cause an inverse effect in the actual cost of labour to perform a scope of work (Selg & Thomas, 2004: CSC.05.1).

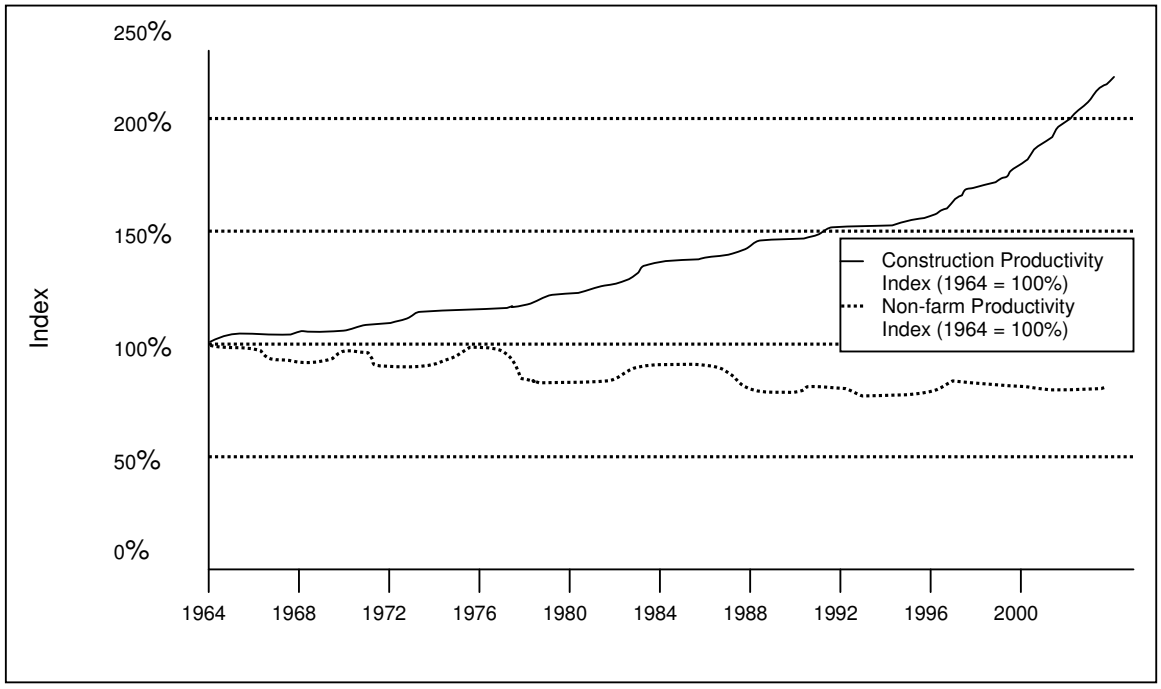

Figure 3.9 Labour productivity index for US construction industry and non-farm industries

Source: Picard and Hutcheson, 2008: PM.11.1\

Several trade specific productivity factors exist. Alinaitwe, Mwakali and Hansson (2007: 169) report on factors affecting building craftsmen. Song and AbouRizk (2006:

EST.25.1) do the same regarding the steel industry while Lee, Lee and Ibbs (2007: EST.05.1) mention factors influencing productivity on freeway construction and Hanna, Peterson and Lee (2002: 331) comment on mechanical and electrical projects. These productivity factors (discussed in Chapter 2 influence the cost of labour on a project.

Bradley (2008: EST.05.1) says that it was during the early 1900's that companies started to accumulate labour metrics. These statistics included what effort hours were required to install the major components such as a cubic yard of concrete, a meter length of cable, a ton of steel, etc. As more companies entered the construction scene competition became tougher and the tendering for new work had to be more dependent on historical data analysis. According to Dumond (2000: 1063), the increased need for a baseline to which all companies could compare or measure their labour productivity was imminent. This sparked the development of the United States Gulf Coast Baseline Worker Hour Norms (USGC). Although this is probably the most well-known tool for estimators in the petrochemical industry, there are other methods and ways of measuring productivity. Park, Thomas and Tucker (2005: 772) describe the Construction Productivity Metrics System (CPMS). This index provides an industry norm for production rates. Zayed and Halpin (2005: 779) use regression models, while Fayek and Oduba (2005: 938) rely on fuzzy expert systems, and Ezeldin and Sharara (2006: 650) use neural networks.

AbouRizk, Knowles and Hermann (2001: 502) show that, especially for labour intensive construction work, the productivity factor is important. The estimator will normally start with an average production rate and then modify it to reflect the expected conditions on site. If the weather is expected to be unfavourable or the skills level is expected to be low, the estimator will increase the number of man-hours required to complete a specific task. In tendering for work in developing countries this activity of altering the average production rate is even more important (Koehn & Jagushte, 2005: INT.03.1). In these countries most construction is carried out using labour intensive methods, making productivity a serious factor to deal with.

Li (2005: CSC.16.1) and Chang, Hanna, Lackney and Sullivan (2007: 287) describe other functional uses for productivity analysis. Schedule adjustment, for instance, is one way where the productivity database can be used to capture possible increases or savings on the schedule. Moselhi, Assem and El-Rayes (2005: 354) indicate that especially in fast track construction, where construction begins prior to design completion, that in the case of change orders, production analysis can be used to more

accurately estimate the possible cost increase. Productivity analysis can also be used to improve construction processes (Cottrell, 2006: 189; Zayed, 2005: 677; Dunlop and Smith, 2004: 55) and labour-flow-planning (Thomas, Horman, Minchin & Chen, 2003: 251). Productivity analysis can even influence scope definition as indicated by Song and AbouRizk (2005: 360). O'Connor and Huh (2005: 1013) and O'Connor and Huh (2006: 408) indicate how productivity can influence the construction schedule.

Luiz (2002: 594) reports on the socio-economical state of South Africa and the post-apartheid economic reconstruction. The new government came with new ideas; some which worked and some which did not work (Easterly, 2007: 330). The apartheid-era went hand-in-hand with economic sanctions, all of which were abolished when the new government took over (Ramabodu, Kotze & Verster, 2007: 7). The main drive behind socio-economical upliftment was planned through executing the Reconstruction and Development Programme (RDP). Especially in the housing sector, construction benefitted from the RDP programme, but later when it became apparent that the programme would fail because of constant political interference (Luiz, 2002: 596) everything came to a standstill.

Andersen (2008: RISK.04.1) states that political interference can be one of the biggest single causes for drastic cost increases on a construction project. He describes how Danish Professor Bent Flyvbjerg proposed recommendations to the Danish government for improving planning on mega projects; one of which was to refrain from political interference. Hand-in-hand with the political influence on the cost to construct a project is the socio-political aspects or cultural differences (Chan & Tse, 2003: 375).

4.6 Project location

Oladapo, Aladegbaiye and Aibinu (2008: 119) state that a good estimator can readily estimate the cost of a project in his area of operation, but it may not always be so for projects outside his familiar area. This can be ascribed to the fact that the estimator will find himself on unfamiliar ground should he venture into unknown areas of operation. Gerber (2008: personal communication) describes the two main considerations in price increases on remote projects as transportation costs and increased labour costs. Unlike factory conditions, construction is different in the sense that the work is not performed in a set factory, but on site which differs in geographical location with every new project.

Oladapo *et al.,* (2008: 120) describe the effect of location on construction prices as twofold. Firstly, institutional factors such as local regulations (laws and by-laws) and the level of taxation, and secondly, market factors that include demand and supply of construction inputs. Generally, the more remote a project location is, the more expensive it will be because of the effect of commodities, such as transport. Algarni, Arditi and Polat (2007: 729) indicate that poor infrastructure (especially in developing countries) also has an effect on the estimated cost.

The only way to counter the effect of location is to incorporate the major influences of location into the calculation of the final estimated cost. The most common way to do this is by means of Location Factored Adjustment (LFA) (Jansen-Romijn, 2008: EST.13.1). Jansen-Romijn (2008: EST.13.1) formulates the definition of a location factor as follows:

> *"A location factor is an overall total project factor for translating all of the project cost elements of a defined construction project scope of work from one geographical location to another."*

This factor recognises differences in productivity and costs of labour, engineered equipment, commodities, freight, duties and taxes, procurement, engineering, design and project administration. Jansen-Romijn (2008: EST.13.1) describes a simplified overview of the location factoring method as follows:

- Selecting a detailed estimate for the base location.
- Creating a parallel estimate by applying overseas labour, material and equipment factors (all developed at a constant exchange rate) to the base estimate.
- Calculating allowances for taxes, fees, input duties, freight, etc. with expected percentages from the foreign location.
- Calculating allowances for procurement, engineering, design and project administration with expected percentages for the foreign location taking into account that part of it cannot be executed locally.
- Dividing the base estimate to the parallel factored/percentage estimate to produce a location factor.

Oladapo *et al.* (2008: 123) describe the specific methodology for the adjustment of estimated costs for regional influences using factors. Three common types of price indices exist to calculate inflation. They are the Laspeyres Index, the Paasche Index and the Fisher Ideal Index. The Laspeyres Index is a base weight index which uses the relative quantities of the base period to provide the weighing of the respective prices. The Paasche Price Index is a current weight index. The Laspeyres Index has been found to overstate inflation while the Paasche Index understates inflation. The Fisher Ideal Index is a combination of the two and has been proven to be the best method (Yu & Ive, 2006: 786).

The basic methodology for the determination of a Location Adjustment Factor (LAF) is described by Jansen-Romijn (2008: EST.13.1). Oladapo *et al.,* (2008: 124) built on this description and developed a basic equation to reflect the effect of location on construction cost. This equation can be put as follows:

$$\text{Location factor A} = \frac{\text{Price of construction at location A}}{\text{Price of construction at location B}}$$

It is important to note that the prices used in this case should have the same base date and that prices of different base dates will result in askewed results.

4.6.1 Supply chain

Schary (1998: 155-156) indicates that the concept of supply chain is not new and that it has been well documented that it occurred from the Renaissance period. Firms have become dependent on their suppliers and require other firms to market their products. Competition does not necessarily lie between individual firms, but in increasing importance between supply chains themselves as supra-organisations. The managerial context of the supply chain combines these two perspectives with a third - close coordination of all operations within the chain from raw materials to ultimate customer, and beyond, to the disposal of the consumed product. Improving the supply chain and the management of this chain can result in a reduction in transport costs. Alvi (2008: 36) and Goodwill (2008: 38) elaborate on the importance of supply chain management.

4.6.2 Transportation

Stock and Lambert (2001: 312) state that an industrialised society cannot exist without an efficient transportation system. It is often assumed that the products will move from where they are produced to where they are consumed with a minimum of difficulty, in terms of both time and cost. In most economies transportation is so pervasive that its effect on society is not realised. In the United States transportation constitutes approximately 6% of the gross domestic product (GDP) (Stock & Lambert, 2001: 312). In 1999 transportation costs amounted to $556 billion in the United States. Figure 3.10 indicates the ratio between freight costs and the GDP. It will be noted that the growth rate of freight costs declined in the years 1980 to 1981 (Gransberg, Lopez del Puerto & Humphrey, 2007: 405). This is due to the economic deregulation during that period of the United States transportation system, as well of the introduction of new technologies and the implementation of many leading edge technologies and management philosophies. Alonso-Villar (2005: 589) also comments on the effects of transport costs.

Shakantu, Tookey and Bowen, (2003: 105) demonstrate the importance of transport in construction with special emphasis on the transport of construction materials. They also state that construction is one of the most cost-orientated industries in any economy and that construction estimates (in general) are based on straight “take-offs” of the quantities required. All further “other” costs in the form of overheads, profit, labour and wastage are consolidated into the cost of the material (Liu & Ling, 2005: 395). Construction is unique within the various industries making up a modern economy in that the bulk of the material and the components that it uses are of relatively low value while being of high volume. Consequently, a significant proportion of the “other” costs associated with material purchases must be in the form of transportation (Shakantu *et al.*, 2003: 105).

Stock and Lambert (2001: 314) name some factors that influence the cost of transportation:

- The degree of intermode and intramode competition.
- The location of markets.
- The nature and extent of government regulation.
- The balance or imbalance of freight traffic in the market.
- The seasonality of product movements.

- Domestic or international transport.

To understand the effect of transport on the cost of a construction project, the different transport modes should be discussed. Figure 3.11 compares the five main modes of transport in the United States of America. Stock and Lambert (2001: 322 - 328) also describe the following five basic transport modes:

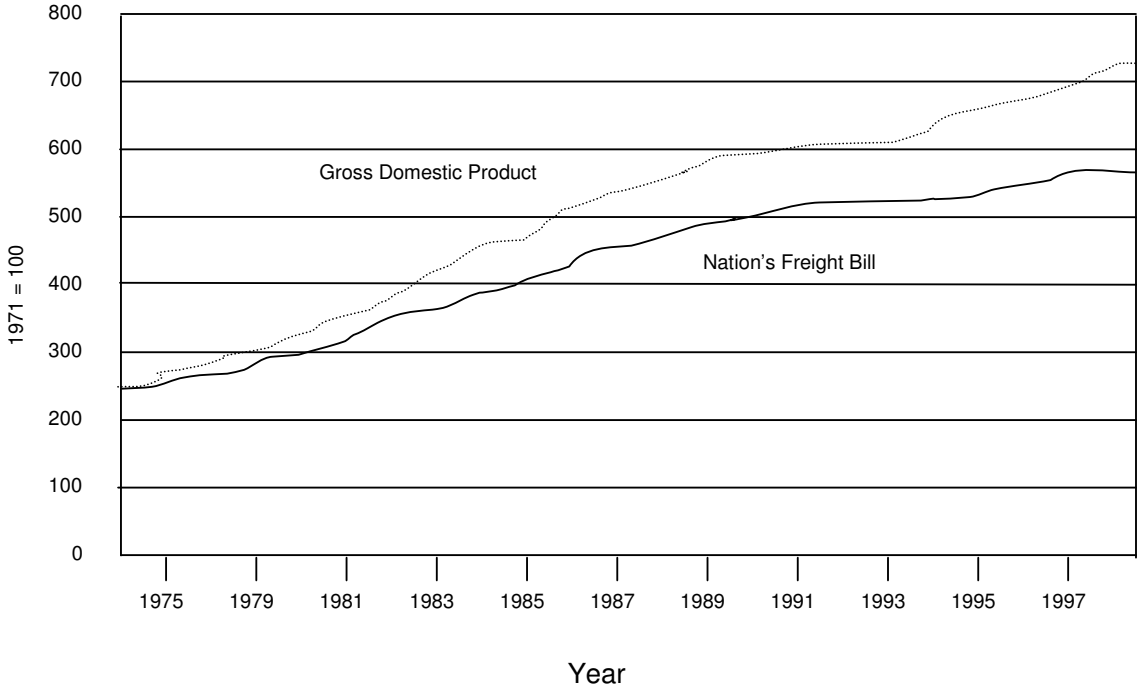

Figure 3.10 Freight transportation outlays versus GDP of the United States
Source: Stock and Lambert, 2001: 312

4.6.2.1 Motor

During the late 1960's motor carriage replaced rail carriage as the dominant form of freight transport in the United States. Motor carriers often compete with air carriers for small shipments and with rail carriers for large shipments. An efficient motor carrier can compete with an air carrier on a point-to-point basis for any size shipment if the distance is less than 1 000 miles (Stock & Lambert, 2001: 323). This is because motor carriers can realise greater efficiencies in terminal, pickup and delivery options (Dennis, 2007: 5).

	Motor	Rail	Air	Water	Pipeline
Economic characteristics					
Cost	Moderate	Low	High	Low	Low
Market coverage	Point-to-point	Terminal-to-terminal	Terminal-to-terminal	Terminal-to-terminal	Terminal-to-terminal
Degree of completion (number of competitions)	Many	Moderate	Moderate	Few	Few
Predominant traffic	All types	Low-moderate value, moderate-high density	High value, low-moderate density	Low value, high density	Low value, high density
Average length of haul	Short to long	Med to long	Med to long	Med to long	Med to long
Equipment capacity (tons)	10 – 25	50 – 12,000	5 – 125	1,000 – 60,000	30,000 – 2,500,000
Service characteristics					
Speed (time in transit)	Moderate	Slow	Fast	Slow	Slow
Availability	High	Moderate	Moderate	Low	Low
Consistency (delivery time variability)	High	Moderate	High	Low	High
Loss and damage	Low	Moderate	Low	Low-moderate	Low
Flexibility (adjustment to shipper's needs)	High	Moderate	Low-moderate	Low	Low

Figure 3.11 Comparison of United States domestic transport modes
Source: Stock and Lambert, 2001: 329

Motor carriers are more flexible and versatile than other transportation modes. The flexibility of motor carriers in the United States is made possible by a network of over four million miles of roads, which enable them to offer point-to-point service between almost any origin-destination combination. Motor carriers are versatile in that they can transport products of varying sizes and weights over any distance. The combination of flexibility and versatility of motor carriage has enabled it to become the dominant form of transport in the United States, as well as many other parts of the world (Stock & Lambert, 2001: 323). Smyrlis (2008: 4) and Westell (2008: 10) elaborate on some modern problems with motor carriage, i.e. congestion and increased rates due to price increases on fuel.

Styan (2010: Fin 24 – 29 April) comments on the steady collapse of the South African railway systems and how this deterioration force companies to make use of road transport instead. Creamer (2008: Engineering News – 16 July) mentions efforts by the

South African government trying to re-instate some of the rail system, but questions are being asked about the economic viability of this effort should it be compared to road transport. The increased usage of the country's road network is causing major damage (Van Wyk, 2010: Die Burger – 25 May). Van Wyk further states costs to repair roads in South Africa are fast becoming a problem that will only be able to be addressed on a national level.

4.6.2.2 Rail

In many regions of the world, such as Europe and China, rail is the dominant transportation mode. In the United States railroads carried over one trillion ton-miles of freight over a track network of 175,000 miles in 1996. Post-World War II saw a decline in the use of railroads and a shift to motor transportation (Stock & Lambert, 2001: 324).

The biggest disadvantage of rail transport is that the rail network is not nearly as extensive as the road network (Cilliers & Nagel, 1994: 10). Rail transport lacks the versatility and the flexibility of motor carriers because it is limited to fixed track facilities. Although the South African situation differs from that of the United States', rail transport has also declined drastically, but Transnet is busy with a drive to shift at least some of the "lost" freight back to rail carriers (Anonymous, 2008s: Accessed 19 November 2008).

4.6.2.3 Air

In the United States air freight represents less than 1% of the total ton-mile traffic. Although increasing numbers of shipments are using air freight for regular service, most view air transport as a premium emergency service because of the higher cost. Putzger (2008a: 6) describes the takeover of Air Canada's Toronto-Frankfurt route by Lufthansa due to increased demand. When products must be delivered to a distant location quickly, air freight offers the shortest time-in-transit of any transportation mode. Contradicting this statement, and probably due to the specific situation in America, Putzger (2008b: 16-18) documents some facts also proving the increased costs of air transportation. US-based company, Boeing, recently had some orders cancelled due to the current poor economic situation in America, but mainly due to the high price of aviation fuel.

Air transport is given to constant enquiries regarding safety and issues pertaining to the safe use of this form of transport. Finger and Piers (2005: 20) describe the effect of the increased safety regulations on the air freight costs in Switzerland. Barbot (2005: 110) expresses similar views.

4.6.2.4 Water

Stock and Lambert (2001: 327) elaborate on the use of water transport. Water carriage can be divided into two main categories: inland waterways and ocean/marine transport. In South Africa there is no inland transport of any economic significance due to the fact that there are no significant waterways. Overseas, for instance in Germany, inland water transport amounts to 20% of all freight transported. In the Netherlands and Norway it is much higher. Water carriage is perhaps the cheapest method of shipping high-bulk low-value commodities.

Marine transport has played an increasing role in the international transport arena. Large container ships and super-tankers have paved the way for bulk transport of items such as coal, crude oil, etc. Water carriage especially is of value where the speed of delivery of the material is not a high priority. Brooks and Button (1996: 21-22) elaborate on the pricing methodology of shipping rates and how marine transport cost is influenced.

4.6.2.5 Pipeline

Natural gas and crude oil account for the majority of pipeline traffic. Coal is also grind into dust. Water is added and the slurry is then pumped through a pipeline. Bausbacher & Hunt stated that pipelines are able to deliver products on time because of the following factors:

- The flows within the pipeline are monitored and controlled by computer.
- Losses and damages due to pipeline leaks are extremely rare.
- Climatic conditions have a minimal effect on products moving in pipelines.
- Pipelines are not labour-intensive and labour-related issues have little effect on them.

The minutes of a meeting (2002: Accessed 19 November 2008) describes Sasol's intention to start development of the natural gas line from the Temane Pande gas fields in Mozambique to Secunda in South Africa. Anonymous (2002: 01 January) describes the start of this project. Hill (2007: 13 September) refers to the R11 billion fuel line Transnet-contract to pump fuel from Durban to Johannesburg and how this pipeline will lesson then current tanker road transport.

4.7 The estimator (the human factor)

Estimating the cost of a construction project involves the gathering, organising and presenting of many pieces of information to make a whole and eventually arriving at a cost for a particular project (Rajpatty, 2008: DEV.12.1; Janssen & Yang, 1999: 501). Doing this requires a person with special skills. Especially in the fast-track type construction that occurs in modern times, the estimator must sometimes analyse poor information and add missing information based on experience (Fellows & Liu, 2000: 362).

McDowell (2008: EST.18.1) indicates that the main attribute of an estimator should be an inquisitive mind. Possible outcomes should be considered to reduce any possible oversights. This is a skill that will only be developed over time. McDowell (2008: EST.18.1) shows that in order to estimate the costs required to provide complete and operable systems, all related items, elements and components must be included. The practical execution of the construction work should therefore be questioned (Hannon, 2007: IT.03.1). A sound knowledge of construction methodology, basic process engineering, project management, planning, etc. is therefore necessary. Richards (2008: EST.01.1) also comments on the skills of the estimator. The estimator should be able to envision a project as it appears built and envision the steps required to build it. All of this should be done by considering the budget.

5.0 ELEMENTAL STRUCTURE OF A PROCESS PLANT

Humphreys (1991: 374) illustrates the basic structure of a cost estimate in Figure 3.12. The definitions and influences of each cost type have been discussed in Chapter 2. Further discussions on the influences of these cost types will follow.

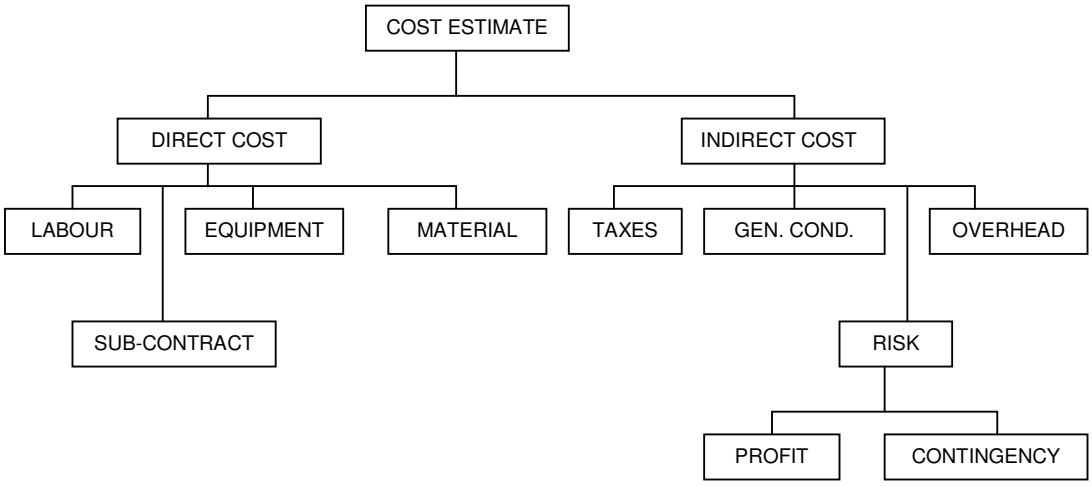

Figure 3.12 Components of a cost estimate
Source: Humphreys, 1991: 374

McAuley (2008: HPG.04.2) and The Association of Cost Engineers (1991: 3) state that construction plants are not standard and the differences arising from the type of construction, building, plant or process, together with the special requirements relating to climate, local regulations, conditions, customs and resources, are numerous (Alinaitwe, 2008: 74). Addendum A refers to an estimating checklist for capital projects and can be used as an *aide-mémoire* that outlines the elemental structure of a typical process plant.

6.0 TYPES OF ESTIMATES, THEIR USE AND APPLICATION

Tam (2007: 6) cites Luke Chapter 14 verse 28 - 30 from the Holy Bible which probably proves the importance of cost estimating, when dealing with construction work, best.

> *"Suppose one of you wants to build a tower. Won't you first sit down and estimate the cost to see if you have enough money to complete it? For if you lay the foundation and are not able to finish it, everyone who sees it will ridicule you, saying, 'This person began to build and wasn't able to finish.'"*

From this verse one can deduce that some type of estimating method for construction cost was used as far back as 2 000 years ago. Tam (2007: 6) also quotes from writings from the ancient Chinese civilisation of 5 000 years ago:

> *"When a rich man wants to build a house, he must first estimate the resources at his disposal and then determine the size of the house to build and ask in what amount materials and labour are needed, how long it will take, and where to get the materials such as earth, stone, bamboo and reeds. The architect will tell him where to get the materials required and how much is the cost and labour involved. By following his advice, the man is able to complete the construction of the house on schedule. It is due to the fact that everything has been carefully planned ahead that the new house is found all in order."*

Pheng (2007: 193) also refers to ancient Chinese literature which mentions calculations which captured time-cost studies and the development of work units indicating the amount of work that a skilled artisan can accomplish in one day. This system is still being used today. Pheng (2007: 195) also refers to master craftsmen who had the responsibility of estimating the materials and labour required for a certain project. He goes on to discuss ancient formulas for calculating volumes and areas of material.

Bowyer (1973: 229-235) mentions the situation in Roman times as described in the book Vitruvius, written 100 AD. Advice was, for example, given as to the methodology of levelling. This contributed to the development of mass earthworks and ultimately in the estimating of costs for such works (Lofton, 2006: OWN.02.2). Vitruvius also referred to the importance of the economic value of construction and stated that construction is not only about the aesthetics. It also referred, for example, to the management of materials. Bowyer (1973: 229-235) also mentions the situation in the 17th century with the Great Fire in London in 1666. The amount of construction work involved in rebuilding London was too much for architects to handle and a specialised position for the quantity surveyor was created. Tam (2007: 11) discusses estimation during the Middle Ages where Free Masons (the highest ranked masons) kept records of costs.

It was essentially the introduction of computers that boosted the evolution of the estimating process in all industries. Karshenas (2007: IT.06.1) and Richards (2005: EST.12.1) describe some aspects of computer applications in estimating. Masmoudi,

Bouaziz and Hachicha (2005: 298-299) describe how computers can be applied even in defined estimating procedures such as welding operations.

Dysert (2004: 9.4) states that although modern estimating is based on proven methods, these methods get more defined with the increase in technology and data from previous projects. World events such as World War II, space travel, the current war in Iraq, etc. almost always lead to a surge in improving estimating models. It is therefore not surprising that some of the most complicated and advanced estimating models in existence were developed by NASA and the American Defence Force, with most of the ground work conducted in the mid-Fifties following World War II.

Modern design enables architects and engineers to do designs more accurately and faster than their predecessors (Grant, Jones & Vlachos, 2007: 20). Because of technology, different estimating processes can be used. Model-based estimating is one example (Kraus, Watt & Larson, 2007: IT.01.1; Tas & Yaman, 2005: 253). Computer designs can be imported into different computer estimating software packages to determine construction cost. Kraus *et al.,* (2007: IT.01.1) refer to Building Information Modelling (BIM) as an example.

Barmania and McMullan (2006: IT.01.1) mention neural networks and artificial intelligence being incorporated into the estimating techniques, thus leading to the commonly used term “intelligent estimating”. Ezeldin and Sharara (2006: 650) offer good examples of where neural networks are employed in productivity analysis in concreting activities. Barmania and McMullan (2006: IT.01.1) refer to three dimensional modelling as a way of performing an estimate. In this technique modelling software is used to model all disciplines including equipment, piping, structural steel, HVAC, electrical, and instrumentation. The three dimensional model can then be used for scope definition, as well as upgraded estimate quantities throughout the project design, and can therefore assist with trending on the project (Hanvey, 2008b: Accessed 2 October).

Richards (2005: EST:12.1) also stresses the fact that although computers can be very useful in estimating, they should only be used to assist and should not completely take over the process. The estimator will not be able to eliminate activities such as physical site visits, consideration for unique project aspects, etc.

6.1 Different types of estimates

Uppal (2007: EST.03) refers to estimating as the key to successfully completing any project from conception through detailed engineering, construction and successful start-up. He warns though that estimating is an approximation procedure that provides answers with significantly less than 100 percent probability of being correct or even close. As previously mentioned in this chapter, Uppal (2007: EST.03) also stresses the importance of scope definition before any estimate can start.

To understand the different methodologies of estimating it is necessary to define what an estimate is. Uppal (2007: EST.03) defines it as follows:

> *"An estimate is a prediction of quantities, cost and/or resources required by the scope of an asset investment option, activity or project. As a prediction, an estimate must address risks and uncertainties. Estimates are used primarily as inputs for budgeting, cost or value analysis, decision making in business, asset and project planning, or for project cost and schedule control processes. Cost estimates are determined using experience and calculating and forecasting the future cost of resources, methods and management within a scheduled time frame. Included in these costs are assessments and an evaluation of risks."*

Clark and Lorenzoni (1985: 5) also emphasise the fact that an estimate is only a prediction based on the knowledge at hand. Dysert (2006: EST.01.1) defines a cost estimate as follows:

> *"Cost estimating is the predictive process used to quantify, cost and price the resources required by the scope of an investment option, activity or project. The output of the estimating process, the estimate, is typically used to establish a project budget."*

Lukas (2006: EST.03.1) reiterates both Clark and Lorenzoni's and Dysert's definitions of cost estimating by using terminology such as "*… rough calculation…"* and *"… approximate computation…"*, again stressing the point that an estimate is nothing more than a prediction of what the end cost of the project will be based on certain variables.

Dysert (2004: 9.5) states that the method of estimating depends on some factors, i.e. the end use of the estimate, the amount of time and money that is available to prepare the estimate, the estimating tools and data available, and the level of project definition and design information available. Zack (2007: 3) and Han and Park (2008: 199) stress the importance of cost estimates and highlight two important facts pertaining to estimating:

- Client decision-makers rely on estimates to make business decisions.
- Estimating involves more than looking up past numbers and factoring it for size, location and time.

Zack (2007: 4) points out his concern regarding some modern estimators who rely heavily on computer software and who produce estimates without applying some form of judgement. Factors influencing productivity, escalation, construction programme, construction methodology, etc. all play a role in estimating and should be considered (Sandberg, Hetland & Tolo, 2005: EST.21.1). Richards (2008: EST.01.1) gives the following guidelines that should be examined when doing an estimate:

- Estimating should be implemented early.
- Estimating involves more than counting.
- The entire project team must be involved in the estimate.
- Accuracy in estimating is in the details.
- What is not in the estimate is as important as what is.
- Estimate organisation must be carefully considered.
- Current information is key.
- Estimating done right serves as a check on project scope.
- An estimate should not be high or low, but just right.
- An estimator must be visionary.

Richards (2008: EST.01.1) continues that the estimate is more than a simple translation of technical project information into financial terms. An estimate should serve as a check of scope with the established budget (Munde, 2003: 144). The process of developing an estimate should be used as an opportunity to verify agreement between the various project documents. If the estimate is not developed early enough in the design process, the estimate becomes only a limited financial forecasting tool. If the estimate is put off until the end of the design, any forecasting

attempts are of little help and required changes are made only through major effort and may jeopardise continuation of a project.

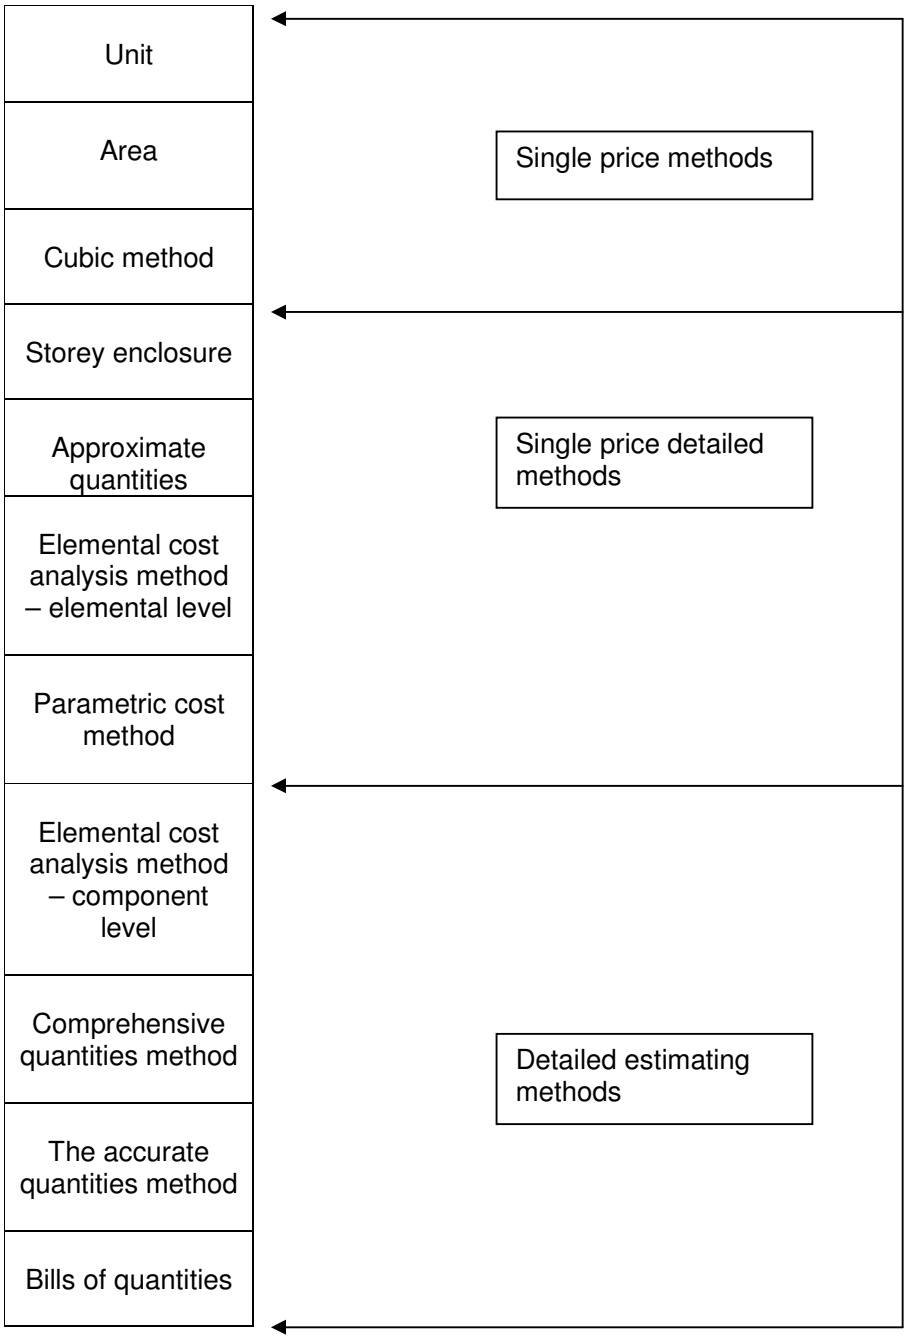

Figure 3.13 Traditional cost modeling – arranged from simple to complex

Source: Ferry and Brandon, 1980: 103

Estimating models differ depending on what industry the estimate must be conducted in. Technology is ever-changing and leads to improved methods for estimating. In the construction sector there are also different trends in estimating. Building construction

estimating is to a large extent based on principles set by quantity surveyors and architects. Figure 3.13 illustrates the traditional cost modelling types that are employed in the building construction industry. For the purpose of this study it will, however, not be necessary to describe these methods in detail.

The engineering construction sector employs different types of estimating models that provide improved answers and are industry specific. According to Dysert (2004: 9.4), two main types of estimates are used in the engineering field, and more specifically in the petrochemical industry. These are “conceptual” and “deterministic” estimating methodologies. Several authors refer to different estimating types within these two main methodologies. Zastrozny (1974: 40) refers to “order of magnitude, economic study, board, check and detailed” estimates. Dysert (2004: 9.5) refers to terms such as “end-product unit method, capacity factor method, ratio or factor methods”, and the “parametric method.”

As the level of project definition increases, the estimating methodology tends to progress from conceptual (stochastic or factored) methods to deterministic methods (Vilela & Longo, 2008: INT.11.1 and Uppal, 2007: EST.03). With conceptual estimating methods, the independent variables used in the estimating algorithm are generally something other than a direct measure of the units of the item being measured. They usually involve simple or complex modeling (or factoring) based on inferred or statistical relationships between costs and other typically design-related parameters (Musgrove, 2007: EST.19.1). For deterministic estimating methods, the independent variables used in the estimating algorithm are more or less a direct measure of the item being estimated, such as straightforward counts or measures of items multiplied by unit costs. Deterministic estimates require a high degree of precision in the determination of quantities, pricing and the completeness of scope definition (Zastrozny, 1974: 40).

Shah *et al.,* (1996: 347) and Pickett and Elliott (2007: EST.02.1) state that there is another key difference between conceptual and deterministic estimating methods. Conceptual estimating methods require a significant effort in data-gathering and methods development before estimating preparation can begin. There is a significant effort in historical cost analysis to develop accurate factors and estimating algorithms to support conceptual estimating (Farkas & Uys, 2004a: 1). Preparing the conceptual estimate itself takes relatively little time (Muscianesi, 2003: 2).

It was previously stated that in contrast to the above mentioned, a deterministic estimate (detailed estimate) requires a large effort during the preparation of the estimate (Kwak & Watson, 2005: 1430). The evaluation and qualification of the project scope can take a significant amount of time (Sharma & Lutchman, 2006: 16.1). Research and application of accurate pricing information and application of specific estimating judgements to the quantified scope can also add to this time consuming process.

As previously mentioned, the specific methodology for estimation to be used depends on various factors, but most of all on the level of design that has been completed. Estimate classification is also discussed later in this chapter.

6.1.1 Conceptual estimates

Conceptual estimates are typically used for low level accuracy estimates to assist management in early stage decision-making. These estimates are often referred to as "order-of-magnitude" or OOM estimates in reference to their typical wide range of estimating accuracy (Zastrozny, 1974: 41). They provide a relatively quick method of determining the approximate probable cost of the project without the benefit of detailed scope definition. Conceptual estimates are typically used for the following purposes:

- Establishing an early screening estimate for a proposed project or programme.
- Evaluating the general feasibility of a project (Kinney & Soubiran, 2004: EST.15.1).
- Screening project alternatives (such as different locations, technologies, capabilities, etc.)
- Evaluating the cost impacts of design alternatives.
- Establishing a preliminary budget for control purposes during the design phase of the project (Serpell, 2005: EST.13.1).

Conceptual estimates are generally based on little project information, for instance engineering deliverables, thus subjecting it to a wide range of estimate accuracy. Serpell (2005: EST.13.1) indicates that their accuracy can depend on several factors, including the level of project definition, the quality of the past historical cost data (Pickett & Elliott, 2007: EST.02.1) in development of the factors and algorithms, as well

as the judgment and experience of the estimator. These limitations should be recognised in using conceptual estimating methods. Nonetheless, there can be cases where conceptual estimates can be very reliable, especially in estimating repeat projects (Sonmez, 2004: 677). Generally, the emphasis with conceptual estimating is not on detailed accuracy, but on obtaining a reasonable cost estimate of sufficient accuracy to ensure that the results are meaningful for management to make the decision at hand (Dysert, 2008: EST.03.1).

It is an accepted practice throughout the petrochemical industry to make important business and design decisions early in the evolution of the project. The result is that the ultimate costs of a project are dramatically influenced by those early decisions made during the process design stage of the project (Kinney & Soubiran, 2004: EST.15.1). Kinney and Soubiran also indicate in Figure 3.14 the importance of accuracy in conceptual cost estimating.

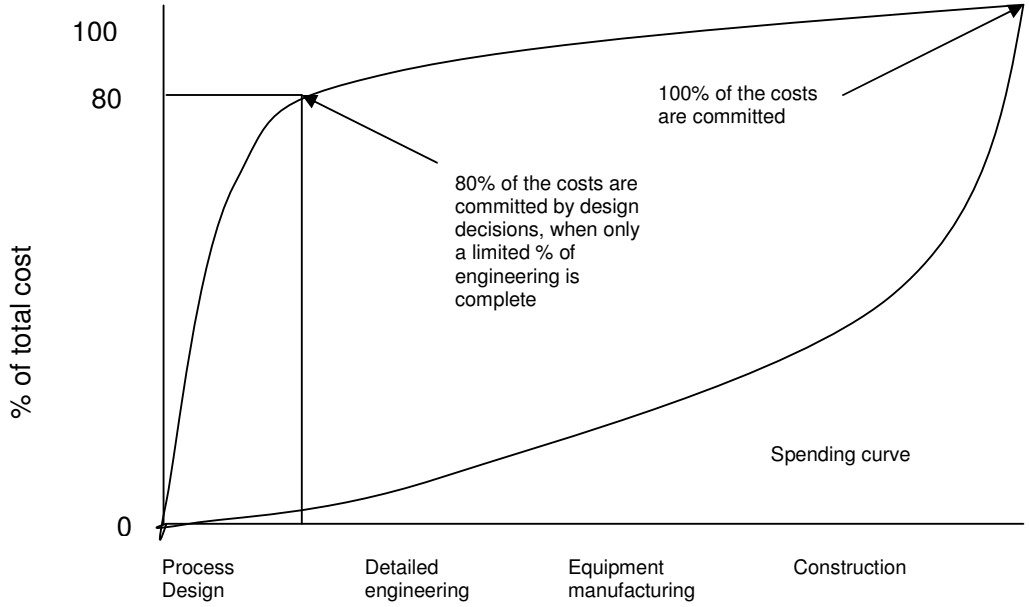

Figure 3.14 Importance of accuracy in conceptual estimates
Source: Kinney and Soubiran, 2004: EST.15.1

6.1.1.1 End-product units method

This conceptual estimating method is used when the estimator has enough historical data available from similar projects to relate the end-product units (capacity units) of a

project to its construction costs (Ellsworth, 2007: 26). This allows an estimate to be prepared in a relatively short space of time. It is, however, necessary to know the end-product unit capacity of the proposed plant. Examples of such an end-product can be the gallon-per-day production of a fuel refinery or the kilowatt output of a power station.

This type of estimate is useful in determining the cost of a proposed project when only the bare minimum is known. As previously stated, only the expected production capability is necessary as a benchmark (Kwak & Watson, 2005: 1430). It is therefore very useful in early stage feasibility analysis to make the initial go-no-go decision.

A direct correlation between different plants based on their output will, however, not reflect the actual movement of costs as projects become bigger or smaller depending on their output. Economies-of-scale are, for instance, ignored. Experienced estimators can make data adjustments to accommodate these changes to an extent. Most of the external factors that can influence an estimate's accuracy are, however, ignored if this methodology is used. Oladapo *et al.,* (2008: 119) indicates how special adjustments are necessary to allow for project location, timing, etc.

6.1.1.2 Physical dimensions method

This method is very similar to the end-product unit method. It has similar uses and similar limitations. Tam (2007: 13) indicates that it is employed in the building construction sector where plan sizes of similar buildings and building heights can vary and simple adjustments are made to accommodate these changes in design. In the petrochemical industry this method is not often employed, but it can be useful when performing semi-deterministic estimates (Dysert, 2004: 9.5), but then only on specific items such as area finishing, buildings that form part of the plant design, etc.

6.1.1.3 Capacity factor method

Ellsworth (2007: 26) demonstrates that a capacity factor method is one in which the cost of a new facility is derived from the cost of a similar facility, but usually with a different capacity. It relies on the non-linear relationship between capacity and cost. The ratio of costs between two similar facilities of different capacities equals the ratio of the capacities multiplied by an exponent:

$$\$B / \$A = (Cap_B / Cap_A)^e$$

Where $A and $B are the costs of the two similar facilities, and Cap_B and Cap_A are the two capabilities of the facilities. This is demonstrated in Figure 3. 14. If this equation is rewritten it becomes:

$$\$B = (\$A)\ (Cap_B / Cap_A)^e$$

Where:

$B is the cost of the facility to be estimated,
$A is the known cost of a similar facility,
Cap_B is the capacity of the facility being estimated,
Cap_A is the capacity of the similar facility, and
"e" is the exponent or proration factor.

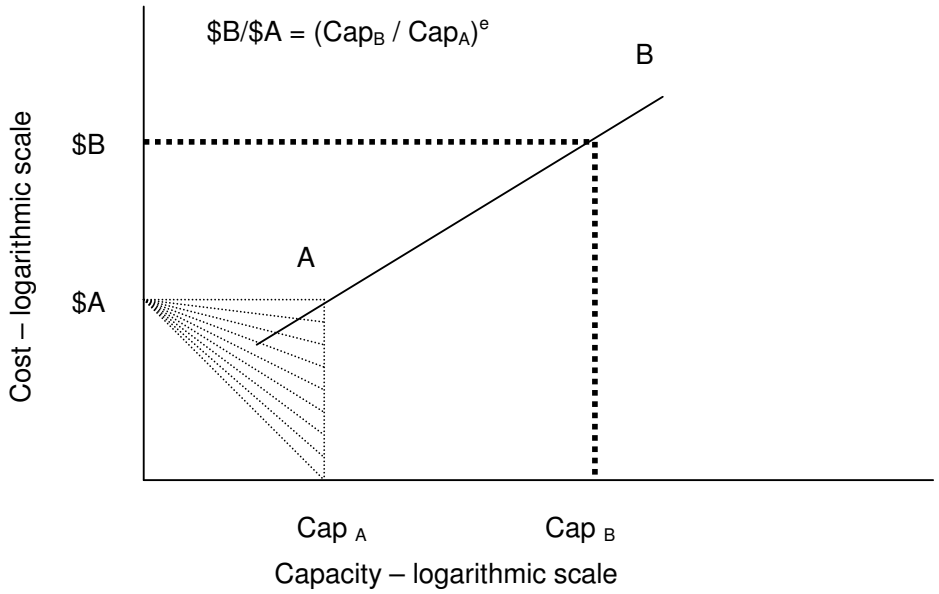

Figure 3.15 Capacity factor relationship
Source: Dysert, 2004: 9.6

Ellsworth (2007: 27) shows that the exponent "e" typically lies between 0,5 and 0,85 depending on the type of facility, and should be carefully analysed for its applicability to each estimating situation. The exponent used in the capacity factor equation is actually the slope of the curve that has been drawn to reflect the change in cost of a facility as it is made larger or smaller. These curves are usually drawn from the data points of the known costs of completed projects. With an exponent value less than 1, scales of economy are achieved such that as facility capacity increases by a percentage, the

costs to build the larger facility increase by less than the same percentage (Ellsworth, 2007: 27).

Dysert (2004: 9.6) indicates that the methodology of using capacity factors is sometimes referred to as the "scale of operations" method or the "six tenth's factor" method due to the common reliance on an exponent value of 0,6 if no other information is available. With an exponent value of 0,6 doubling the capacity of a facility increases the cost by approximately 50 percent, and tripling the capacity of a facility increases the cost by approximately 100 percent.

Dysert (2004: 9.6) says that it is important to realise that as the graph gets plotted, it appears to be in a straight line over a small range of capacity values. It is, however, not constant over the entire range of possible capabilities or facility sizes. In reality, as facility sizes increase, the exponent tends to increase as illustrated in Figure 3.16. As an example, between the capacities A and B as illustrated in Figure 3.16, the capacity factor may have a value of 0,6. However, between capacities B and C, the exponent has a value of 0,65. Between capacities C and D, the value of the exponent may have risen to 0,72. Eventually, as the facility capacity increases to the limits of the existing technology, the exponent tends towards a value of 1. At this point it becomes more economical to build two facilities of a smaller size than one large facility. Cost becomes a linear function of capacity, and scales of economy are no longer obtained. Ellsworth (2007: 27) demonstrates Dysert's findings by means of actual plant costs of hydro-electric pumped storage facilities in Table 3.2. Table 3.2 indicates that it is not always the case that plant cost per output unit decrease as plant size increases. The specific design of each facility needs to be taken into account.

Facility	Year	Capacity in MW	Facility cost in 2005 ($)
Bad Creek, SC	1991	1,065	1,705,000,000
Bath County, VA	1985	2,100	3,632,000,000
Bear Swamp, MA	1974	600	464,000,000
Blenheim-Gilboa, NY	1973	1,000	1,083,000,000
Castaic, CA	1972	1,331	1,735,000,000
Eastwood, CA	1987	200	490,000,000
Fairfield, SC	1978	511	535,000,000
Helms, CA	1984	1,053	1,802,000,000

Jocassee, SC	1973	610	529,000,000

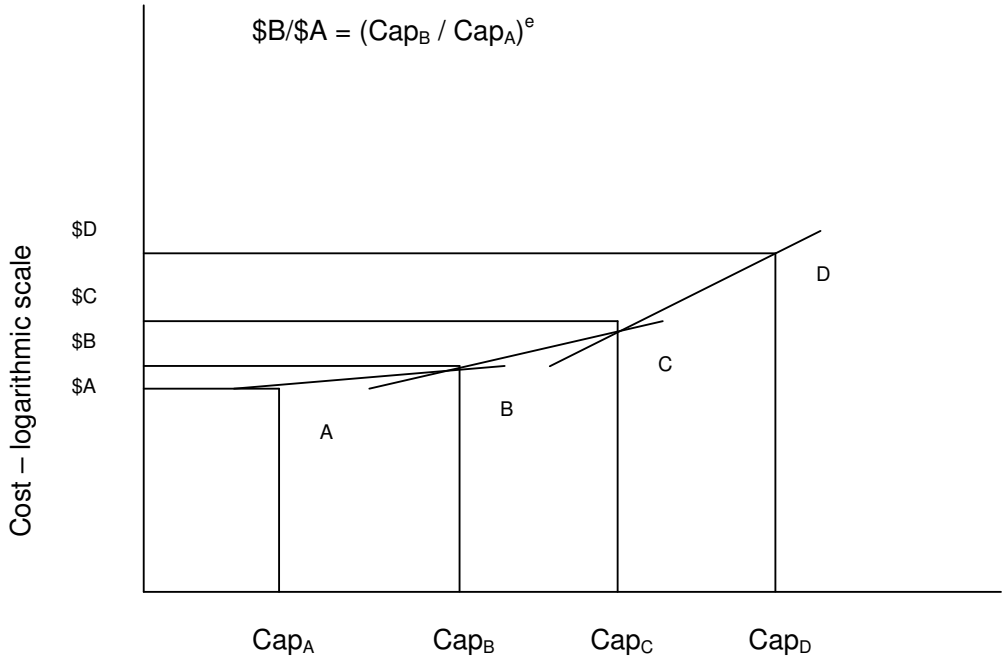

Figure 3.16 Capacity factor exponents are not constant across all capacity ranges
Source: Dysert, 2004: 9.7

This form of estimating can be quite accurate if the capacity factor used in the estimating algorithm is relatively close to the actual value, and if the facility being estimated is relatively close in size to the similar facility of known cost. In a case like this, the potential error from capacity factoring is quite small and is well within the level of accuracy that would be expected from such a method.

Thus, if the facility size being estimated is reasonably close to the size of the known facility, and a realistic capacity factor exponent is used, error from the capacity factoring algorithm is small. However, this error can be compounded by other assumptions that might be necessary to allow for the actual estimating situation such as adjustments for scope, location and time. Each of these adjustments can also add to the level of error in the overall estimate.

The key steps in preparing a capacity factor estimate are described by Dysert (2004: 9.6) and are as follows:

- Deduct costs from the known base case that are not applicable in the new plant being estimated.
- Apply location and escalation adjustments to normalise costs. This determines what the adjusted scope for the base case will cost in the new location and time frame.
- Apply the capacity factor algorithm to adjust for plant size.
- Add any additional costs which are required for the new plant but which were not included in the known plant.

The capacity factor estimating method provides a relatively quick and sufficiently accurate means to provide early estimates during the concept screening stage of a project. The method requires historical cost and capacity data for similar plants and processes. Although published data on capacity factors exist, the best data would be from the specific organisation for which the estimate is being conducted. When using this method the new and existing known facilities should be near duplicates and reasonably close in size. Each of the adjustments that are made, add additional uncertainty and potential error to the estimate. Nevertheless, this estimating method remains a firm favourite when dealing with early stage support decision-making and pre-design estimates.

6.1.1.4 Ratio or factor method

Ratio or factored estimating methods are used in situations where the total cost of an item or facility can be reliably determined from the cost of a primary component. In the case of most petrochemical plants, the specialised process equipment makes up a significant portion of the total project cost. This is often referred to as “equipment factor” estimating (Uppal, 2007: EST.03).

Equipment factor estimates are used to develop costs for process and utility units for which the behaviour of the costs of the direct labour and bulk materials used to construct the facilities is correlated with the costs (or the design parameters) of the major equipment. Liu and Zhu (2007: 91) describe that this estimating methodology typically relies on the principle that a ratio or factor exists between the cost of an equipment item and the costs for the associated non-equipment items (foundations, piping, electrical, etc.) needed to complete the installation.

An equipment factor estimate can typically be generated when project definition is approximately 1 to 15% complete. An equipment list should be available at this point of time in the project. This estimate is often a feasibility estimate used to determine whether there is sufficient business case to pursue the project. If so, then this estimate may be used to justify the funding required to complete the engineering and design required to produce a funding or budget estimate (Newnan *et al.,* 2004: 46).

Depending on the particular factoring techniques and data used, the factors may estimate Total Installed Cost (TIC) or Direct Field Cost (DFC). Usually the factors generate costs only for the Inside Battery Limit (IBL) facilities, and require the Outside Battery Limit (OBL) costs to be estimated separately. Refer to Figure 3.17 (Kinney & Gauche, 2006: EST.14.1). In rare cases there might be sufficient factors to estimate both IBL and OBL at the same time. It is therefore important to understand the basis of the factors used in an equipment factored estimate.

Hans Lang published an article in 1947 where he proposed the use of the total cost of the equipment of a plant multiplied by a factor to calculate the total construction cost of the plant (Uppal, 2007: EST.03). Lang produced three factors which cover all the costs associated with the construction of a plant. This means that it includes IBL as well as OBL costs. Table 3.3 illustrates Lang's factors.

Type of plant	Factor
Solid process plant	3.10
Solid-fluid process plant	3.63
Fluid process plant	4.74

Table 3.3 Lang factors

Source: Dysert, 2004: 9.8

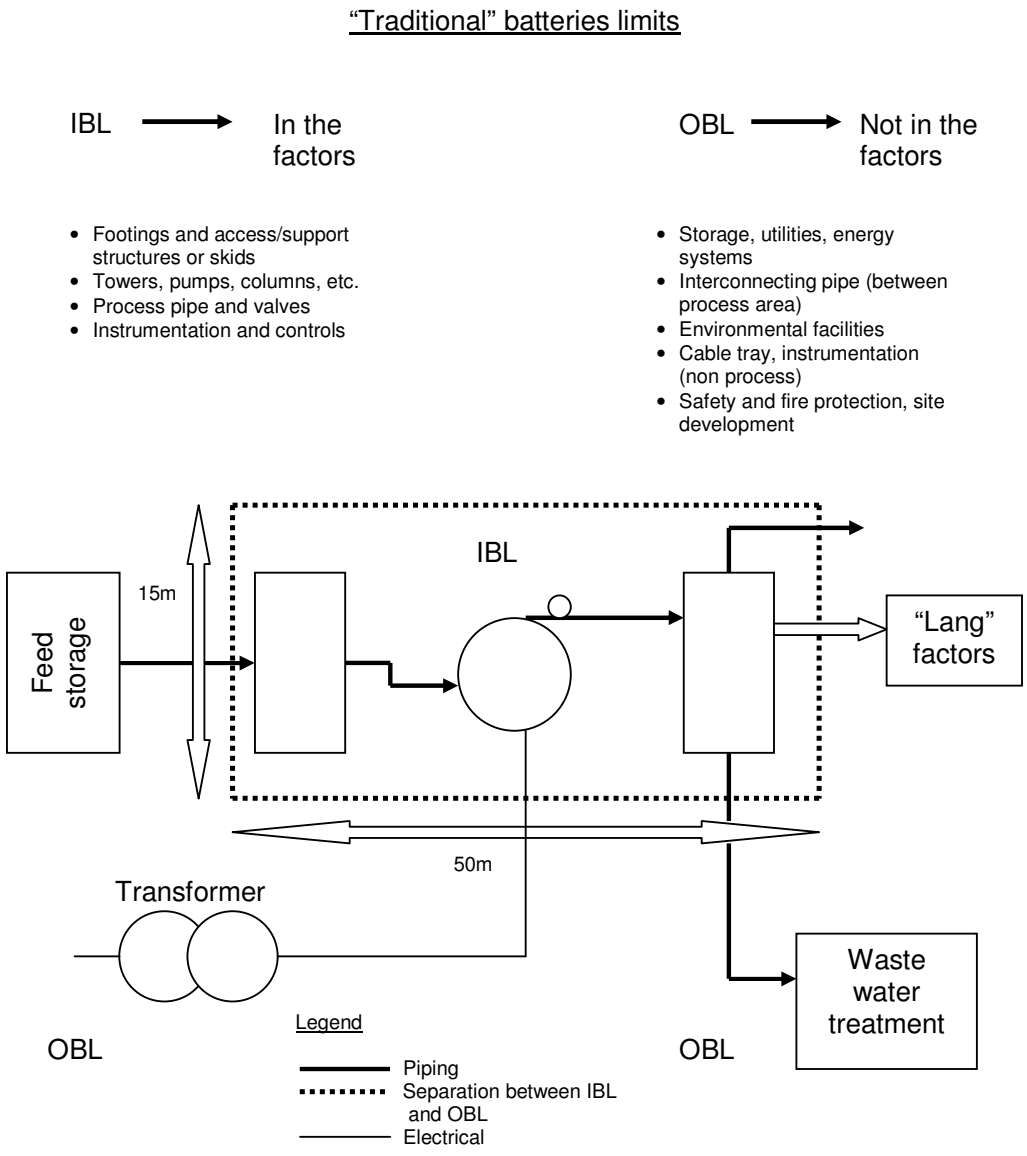

Figure 3.17 Traditional definition of IBL and OBL

Source: Kinney and Gauche, 2006: EST.14.1

Lang's approach was rather simple, utilising a factor that varied only by the type of process. Since that first publication many methods of equipment factoring have been proposed and some have become very sophisticated. The term "Lang factor" is often used to refer to all types of equipment factors.

In 1958 W. E. Hand (Uppal, 2007: EST.03.2) elaborated on Lang's work by proposing different factors for each type of equipment (columns, vessels, heat exchangers, etc.) rather than process type. Hand's factors estimated direct field costs excluding instrumentation. Hand's published equipment factors ranged from 2,0 to 3,5 (which might correlate with 2,4 to 4,3 including instrumentation). Hand's factors excluded indirect field costs, home office costs and the costs for off-site or outside battery limit costs. These costs would have to be estimated separately.

In 1965 Arthur Miller proposed another enhancement to the concept of equipment factors. Miller recognised the impact of three specific variables that affect the equipment material cost to a greater degree than they affect the cost of the associated bulk materials and installation (Dysert, 2004: 9.8). These three factors are the size of the major equipment, the materials of construction (metallurgy) of the equipment, and the operating pressure. Miller notes that as the size of a piece of operating equipment becomes gets larger, the amount of corresponding bulk materials (foundations, support steel, piping, instrumentation, etc.) does not increase at the same rate. Thus, as the equipment increases in size, the value of the equipment factor decreases.

Dysert (2004: 9.8) indicates that similar tendencies exist for an increased quality of material or increased operating pressure. The better the quality of material or the higher the operating pressure, the smaller the factor value. Miller suggests that these three variables could be evaluated in terms of a single attribute known as the "average unit cost" of equipment. The average unit cost of equipment is:

Total cost of process equipment/number of equipment items

If the average cost of equipment increases, then the equipment factor is scaled smaller. The correlation between increasing average unit cost of equipment and decreasing equipment factors was statistically validated in subsequent studies (Nishimura, 1995: 235; Rodl, Prinzing & Aichert, 1985: 112).

The equipment factors described thus far were used to generate all the DFC or the TIC cost. Another method of using equipment factors is to generate separate costs for each of the disciplines associated with the installation of the equipment. Uppal (2007: EST.3.5) describes the use of this methodology. Using this methodology, each type of equipment is associated with several discipline specific equipment factors. For example, one factor will generate the costs for concrete, one for structural steel and one for piping, etc. An advantage of this method is that it allows the estimator to adjust the costs for the individual disciplines based on specific knowledge of the project conditions and improves the accuracy thereof. The estimator can also use the costs for the different disciplines and compare them against other similar costs.

Developing the actual equipment factors to be used in preparing process plant estimates is a time consuming affair. When these factors are used, there should be a clear explanation of what is included in the factors and what not. Equipment factors are typically developed by generating detailed estimates for a matrix of equipment types, size ranges, metallurgies, operating pressures, etc. The estimates are then carefully analysed to develop individual equipment and adjustment factors so that other variables can be accounted for.

The factors developed in this manner can be tested and calibrated against actual project histories. The proposed equipment factors are applied to the actual equipment costs for completed projects, and the result for the factoring exercise is compared to the actual project cost to determine if a reasonable degree of accuracy has been obtained. If the factoring results vary consistently from the actual costs an analysis to determine the reasons will have to be performed. These factors will have to be developed on a continuous basis to improve the accuracy of the method.

When comparing an equipment factored estimate, the first step will be to establish the cost of each piece of equipment. The equipment list should be examined carefully and compared against the process flow diagrams (PFDs). If factored estimating is used, the complete list of equipment is generally not available. Assumptions should be made as to which auxiliary equipment will be used in conjunction with the major pieces of equipment.

Equipment sizing should also be verified. At this preliminary stage of engineering a common problem is that equipment is often sized at 100% of normal operating duty. What typically happens is that by the time the equipment data have been added to the

purchase order, a percentage of over sizing has been added to the design specifications. The percentage of over sizing depends on the type of equipment and the specific company procedures.

The purchase cost of the equipment may be obtained from several methods using purchase orders, other purchase information from recent purchases, published equipment cost data, and firm vendor quotations. Since the material cost for equipment can vary between 20 and 40% for process plants it is important to estimate the costs as accurately as possible. If historical purchase information is used, one should ensure that the costs are escalated appropriately and adjusted for location and/or market conditions as required.

When the equipment cost is established, the appropriate equipment factors need to be established and applied. Adjustments for equipment size, metallurgy and operating conditions are included if necessary. Any specific project or process conditions should be evaluated to determine if scope-based adjustments to the factored costs will be required. A more congested site, for example, will lead to shorter pipe and cable runs due to closer equipment spacing, but the congestion on the site will have a negative effect on productivity. Areas prone to seismic activity probably will require adjustments to the foundations and might include the use of piles or raft foundations.

When the equipment factored estimates are complete, the remainder of the project costs that are not covered by the factors must be estimated. Depending on the type of factors used, this may include indirect field costs, home office costs and outside battery (OBL) costs. A very important factor that should be taken into account when making use of this method is to know exactly what is included in the factors and to include all costs that are not covered by the factors.

6.1.1.5 Parametric method

A parametric cost model is a useful tool for preparing conceptual estimates when there is little technical data or engineering deliverables to provide a basis for using more detailed methods. NASA (Dysert, 2004: 9.11) defines parametric estimating as follows:

> *"A parametric model is a mathematical representation of cost relationships that provide a logical and predicable correlation between the physical or functional characteristics of a plant and its resultant cost. A parametric*

estimate comprise cost estimating relationships and other parametric estimating functions that provide logical and repeatable relationships between independent variables, such as design parameters or physical characteristics and the dependent variables, cost."

Capacity and equipment factor estimates are simple examples of parametric estimates, however, sophisticated parametric models typically involve several independent variables or cost drivers (Brunsman, Robson & Gransberg, 2008: EST.06.1). Though similar to those estimating methods, parametric estimating is reliant on the collection and analysis of previous cost data in order to develop the cost estimating relationships. The process of developing a parametric model should generally involve the following steps (Dysert, 2008: EST.03.2):

- Cost model scope determination,
- data collection,
- data normalisation,
- data analysis,
- data application,
- testing, and
- documentation.

The first step in developing a parametric cost estimate model is to establish its scope. This includes defining the end use of the model, the cost basis of the model, and the critical components and cost drivers (Dysert, 2008: EST.03.2). The end use would typically be to prepare conceptual estimates for process plants. The type of process to be covered by the model, the type of costs to be estimated, the intended accuracy range of the model, etc. should all be determined as part of the end-use definition. The model should be based on actual costs from completed projects, and should reflect a specific organisation's engineering practices and technology (Brunsman *et al.,* 2008: EST.06.1). The model should generate current year costs or should have the ability to escalate costs to current year costs. The model should be based on key design parameters that can be defined with reasonable accuracy early in the project scope development and provide the capability for the estimator to easily adjust the derived cost for specific complexity or other factors affecting the particular project, (Fang & Rogerson, 1999:45).

The quality of the resulting model cannot be better than the data that it is based upon (Polla, 2007: 12). The level at which cost data is collected will affect the level at which the model can generate costs and may affect the derivation of the cost estimating relationships. It is advisable to collect cost data at a fairly low level of detail. The cost data can always be summarised later if an aggregate level of cost information provides a better model. A base date should be recorded for each set of data collected to allow future normalisation. Kwak and Watson (2005: 1431) state that the scope information should include all proposed design parameters or key cost drivers for the model, as well as any other information that may affect costs. It is usually best to create a formal data collection form that can be consistently used, and revised if necessary.

After the data has been collected the next step in the process of developing a parametric model is to normalise the data before it can be analysed. (Dysert, 2008: EST.03.2) states that normalisation of the data involves making adjustments to the data to account for the differences between the actual basis of the data for each project, and a desired standard basis of data to be used for the parametric model. Typically, data normalisation involves making adjustments for escalation, location, site conditions, system specifications, and cost scope.

There are many diverse methods and techniques to analyse the data (Kwak & Watson, 2005: 1434). Further information on these methods will follow further in this study. Typically, data analysis consists of performing regression analysis of costs versus selected design parameters to determine the key drivers for the model.

The data application stage of the development process involves establishing the user interface and presentation form for the parametric cost model (Wong, 2002: 373). Using the mathematical and statistical algorithms developed in the data analysis stage, the various inputs to the cost model are identified, and an interface is developed to provide the estimator with an easy and straightforward way in which to enter this information (International Society of Parametric Analysts and the Society of Estimating and Analysis, 2007: 2.8). Once the regression analysis have been performed and algorithms have been obtained, it must still be examined to ensure that it make sense. If the relationships from the model appear to be reasonable, additional tests can be performed for statistical significance and to verify that the model does provide answers within an acceptable range of error.

A quick test to run is to test the regression results directly against the input data to see the percent error for each of the inputs. This can then be used to determine the range of error, and interpreting the results can assist in determining problems and refining the algorithms. The whole model should be tested against new data (data not used in developing the model). The data used to create the model should be documented, including a discussion on how the data was adjusted and normalised. All the assumptions and allowances designed into the model should be documented, as should any exclusions. The range of applicable input values and the limitations of the model's algorithms should also be explained.

6.1.2 Deterministic (detailed) estimating methodologies

A detailed estimate is one in which each component of a project scope definition is quantitatively surveyed and priced using the most realistic unit prices available (Vilela, & Longo, 2008: INT.11.1). Yepez (2008: 70) points out that detailed estimates are typically prepared to support final budget authorisation, contractor bid tenders, cost control during project execution, and change orders. Detailed estimates use a deterministic approach and require a substantial amount of time and are quite costly to prepare (Tam, 2007: 28).

At a minimum, the required engineering and design data required to perform a detailed estimate includes process and flow diagrams, piping and instrument diagrams, equipment data sheets, motor lists, electrical one-line diagrams, piping isometrics (for alloy and large diameter pipes), equipment and piping lay-out drawings, plot plans and engineering specifications. Pricing data should include quotations from vendors, current pricing information from recent purchase orders, current labour rates, project schedule information, etc.

In a completely detailed estimate, all costs are detailed including direct field cost, indirect field cost, head office costs and all other miscellaneous costs for IBL, as well as OBL facilities. A semi-detailed estimate might include factored IBL costs and measured quantities for the OBL facilities. A forced detailed estimate is one where quantities are taken off preliminary drawings and design information (Dysert, 2004: 9.13). The following steps comprise the activities undertaken during the preparation of a detailed estimate:

- Prepare project estimate basis and schedule.

- Prepare direct field cost estimate.
- Prepare indirect field cost estimate.
- Prepare head office cost estimate.
- Prepare sales tax and duties estimate.
- Prepare escalation estimate.
- Prepare project fee estimate.
- Prepare cost risk analysis / contingency determination.
- Review and validate estimate.

The preplanning of the estimate is essentially the first step in performing the estimate. The estimate basis documents the activities and course of action that will be used to prepare the estimate. The organisation's estimating guidelines and procedures should be reviewed with the estimating team. The project's work breakdown structure (WBS) should be reviewed and an agreement should be reached on the estimating format. The structure of the detailed estimate is mostly used to support cost control during the execution of the project and should be structured to accomplish that purpose. The listing of engineering and technical deliverables should be reviewed. Any exclusion should be documented not to omit these when the estimate is finally submitted. As previously stated, the items not included in the estimate are just as important as those included in the estimate.

Estimating the direct field costs is the most intensive activity of the detailed estimate. Project scope should be reviewed and understood, and all technical deliverables assembled. As the drawings are issued from the engineering department a take-off must be done to quantify all material and labour components in order to cost it later on. Labour hours are assigned to all activities and get adjusted for labour productivity. The direct field cost estimate then is summarised and reviewed for completeness and accuracy.

The labour component of the direct field cost is normally a basis for the indirect field cost estimate. These labour hours are factored to determine what the indirect field cost component will be. The construction manager should be heavily involved in finalising the indirect field cost estimate. The estimator, in conjunction with management, will discuss the sundry items such as tax allowances, profit allowances, etc. to be added to the total estimate (Anonymous, 2008r: 5). An important additional cost will be the

contingency that should be calculated and added to the estimate. More information on contingency calculation will follow in this study.

The costing of the process equipment is as important in the detailed estimate as it is in the equipment factored estimate. Equipment cost will be the most significant cost on the project. The minimum requirements for pricing the equipment will be the process flow diagrams, equipment lists, and the equipment process data sheets. In many cases there will not be enough time to obtain formal quotations for equipment and the estimator will revert to parametric estimating to determine the cost of the equipment. A check between the equipment list and the flow diagram should be standard practice. The estimator should also ensure that all additional items should be included in the price for any given piece of equipment. Freight costs can be significant and should not be forgotten.

Equipment installation costs are usually prepared by the estimator, with assistance from the construction team where required. Construction assistance is usually required when heavy lifts, site access, scaffolding or special installation methods are required. The labour content for the installation of equipment is usually based on the weight of the equipment. Using the equipment weight and physical size, the man-hours required to install the piece are typically determined from production curves based on historical data. Depending on the information available, the labour hours to set and erect a heavy vessel may not include the hours to erect, take down, and dismantle a guy derrick, gin poles or other special lifting equipment. Special consideration may also be given to calibration, soil settlement procedures, special internal coatings, hydro testing and other testing requirements.

As previously stated, detailed estimate is the most accurate form of estimating, but also requires the most time and effort to prepare. In modern construction almost all projects are based on the fast track principle which means that the fully detailed estimate will almost never be used as a pre-contract estimating tool, but rather as an in-contract cost control device. In most cases the semi-detailed estimate or the forced-detailed estimate will prevail. These estimates can be done sooner since they are based on a lower level of detail. This will mean that management will be sooner in a position to make financial decisions as to whether a project should continue or not.

6.2 Estimate classifications

Liu and Zhu (2007: 93) and Aslaksen and Vigerust (2007: RISK.02.2) state that formal estimate classifications have been developed to establish a series of routes to allow the project team to better manage the estimate process. Figure 3.18 shows that for a conventional project the emphasis in the conceptual stage should be on input factors such as project information and team experience. In the design stage, attention is shifted to estimation design and estimation process, in addition to project information and team experience. Entering the tendering stage, the focus is on expected accuracy level, benchmarking, and team alignment, in addition to estimation design and estimation process. Finally, at the construction stage, focus narrows further down to review and acceptance of estimate, estimation design, team alignment and benchmarking (Liu & Zhu, 2007: 93).

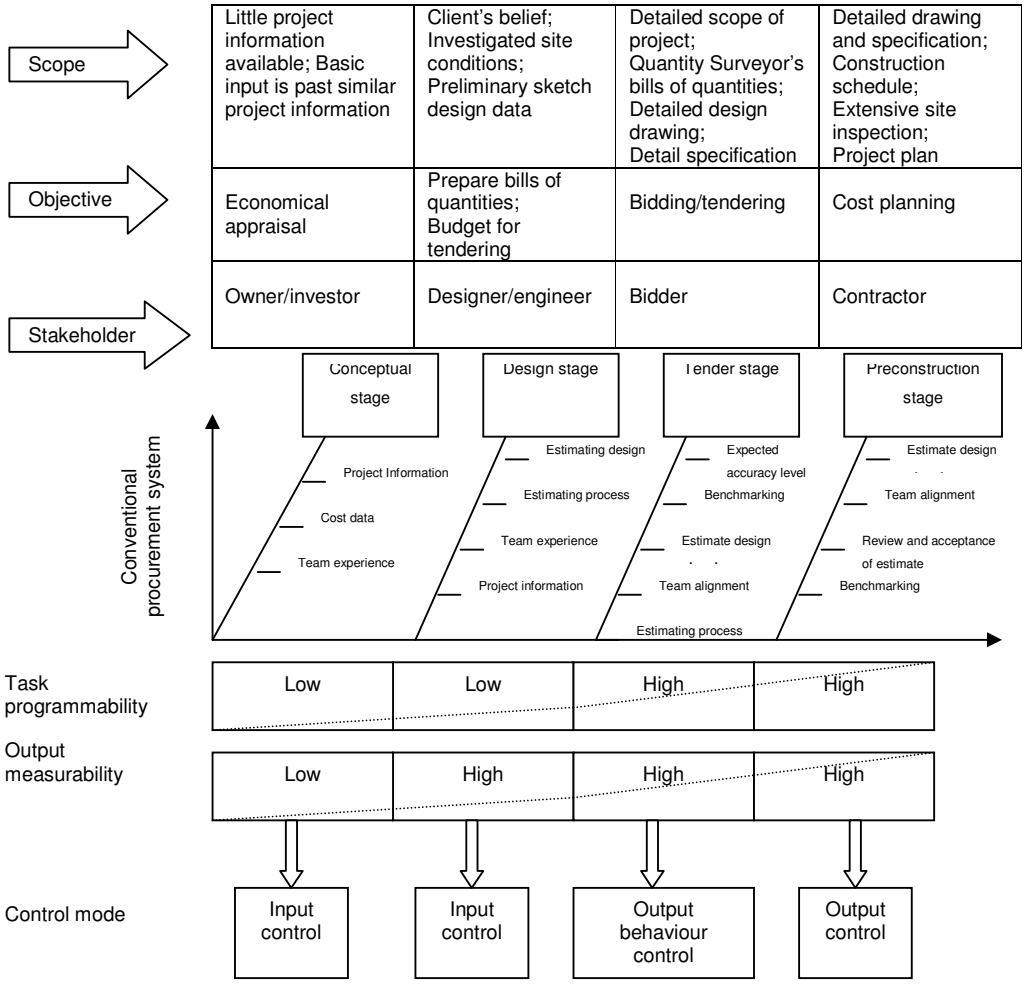

Figure 3.18 Stage-by-stage controls factors framework

Source: Liu and Zhu, 2007: 93

To obtain the various levels of accuracy (as proposed by Liu and Zhu) certain types of estimates were labelled, assigned to certain levels or classifications. Molenaar (2005: 343) comments that cost estimates should transparently convey the true nature of uncertainty involved with the project at each stage of the process. Estimating procedures must model both the technical and non-technical nature of the challenges in quantifying capital costs early in the project's life cycle.

Molenaar (2005: 344) states that cost estimating techniques and tools should relate and adapt to the various phases of project development. Molenaar (2005: 344), Barmania and McMullan (2006: IT.01.2) and Uppal (2006: EST.07.4) describe the estimate classification system of The Association for the Advancement of Cost Engineering International (AACE). Table 3.4 illustrates this proposed classification system. The system described in Table 3.4 is fairly similar to the generic cost estimate classification matrix proposed by AACE.

Estimate class	Engineering complete	Typical contingency	Typical estimate accuracy	Purpose of estimate	Required for PA gate
5	Minimal	-	± 50%	Evaluation Screening	1
4	1 – 10%	15 – 25%	- 15% + 30%	Concept selection FEED decision	2
3	10 – 25%	10 – 15%	- 10% + 15%	AFE Project sanction decision	3
2	30 – 80%	5 – 10%	- 5% + 10%	Control estimate Re-forecast of Class 3	
1	80 – 100%	0 – 5%	- 3% + 7%	Final control estimate Re-forecast of Class 2	

Table 3.4 AACE estimate classification

Source: Barmania and McMullan, 2006: IT.01.2

The system allows for an expected range of accuracy for each phase. A Class 5 estimate is based on the lowest level of project definition and a Class 1 estimate is close to full project definition. Table 3.4 also describes the methodological approach to the estimate as either stochastic or deterministic, depending on the level of design and information available.

Figure 3.19 and Figure 3.20 explain how identifying, quantifying and managing cost and schedule uncertainties relate to management of the cost of major projects. Figure 3.20 applies to situations where the scope is unchanged and where an estimate at some early stage (e.g. 5% design stage) has included uncertainty. There should be a reduction in the range of cost or schedule uncertainty as a project proceeds from concept to completion. The reduction in estimated cost is as a result of better defining cost variables and eliminating uncertainty as cost factors are finally incorporated into the project plan (Molenaar, 2005: 344).

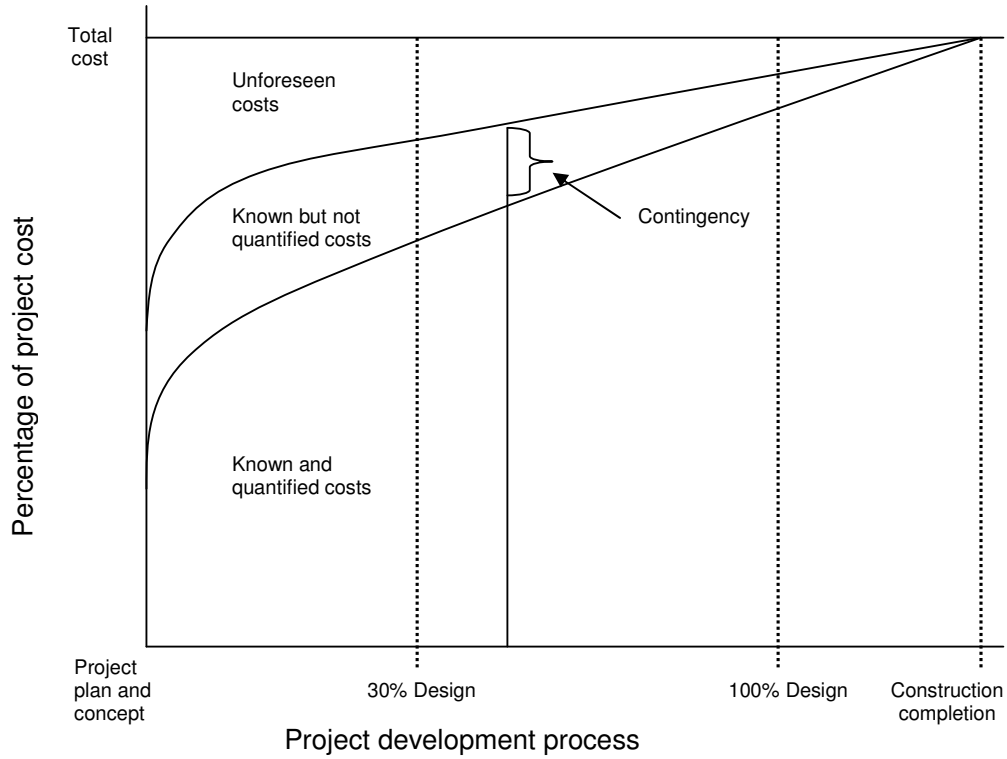

Figure 3.19 Conceptual components of a cost estimate

Source: Molenaar, 2005: 344

6.3 Take-off

The traditional quantity surveying profession is most familiar with quantity take-offs. Bills of Quantities are based on quantity take-offs and are thus an essential part of a quantity surveyor's function in the professional team. In the engineering field, the total responsibility is shared by the quantity surveyor, as well as the cost controller/cost engineer. The main difference in taking off for tendering purposes as a consultant on the client's side and that of a take-off for an estimate for tendering purpose is probably that the estimator on the contractor's side does not have the luxury to include provisional measures and provisional amounts that can later be re-measured (Claasen, 2008a: Financial Mail – 25 April). More clients tend to opt for the "Lump Sum Fixed Price" type contract and in the case of a design-construct contract will hold the contractor responsible for under-measuring the tender (Henschel & Hildreth, 2008: CDR.S02.1).

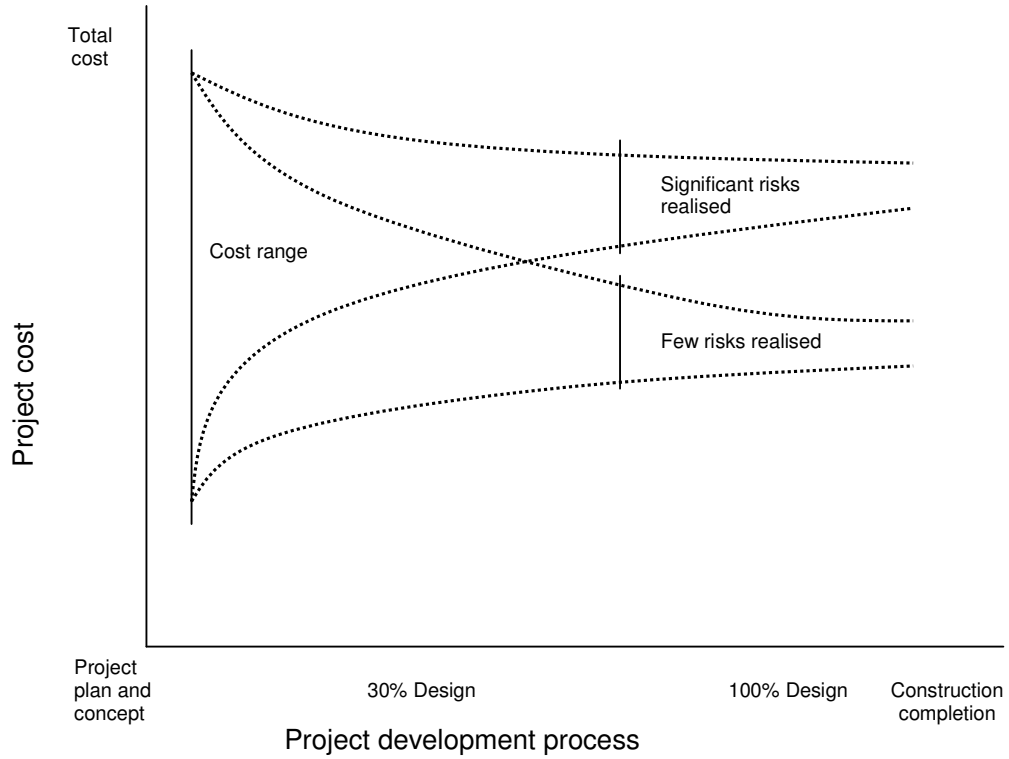

Figure 3.20 Conceptual refinement of a cost estimate

Source: Molenaar, 2005: 345

Take-offs are an essential part of detailed estimates (Dysert, 2004: 9.18). By keeping a uniform and consistent take-off process, the chance of error or omission is reduced.

This will enable new estimators on the team to pick-up much easier where the previous estimator left off. It is not necessary to discuss the basic principles of take-offs here, but should the estimator keep to these principles he will seldom experience a problem in these tasks.

6.4 Estimating allowances

Harbuck (2007: EST.16.2) demonstrates in Figure 3.21 the change in construction variables during the course of construction. Allowances are often included in the estimate as a percentage of some detailed cost component. Harbuck (2007: EST.16.2) indicated some typical examples of allowances that may be included in detailed construction estimates:

- design allowances for engineered equipment,
- material take-off allowances,
- overbuy allowances,
- unrecoverable shipping damage allowances, and
- allowances for undefined major items.

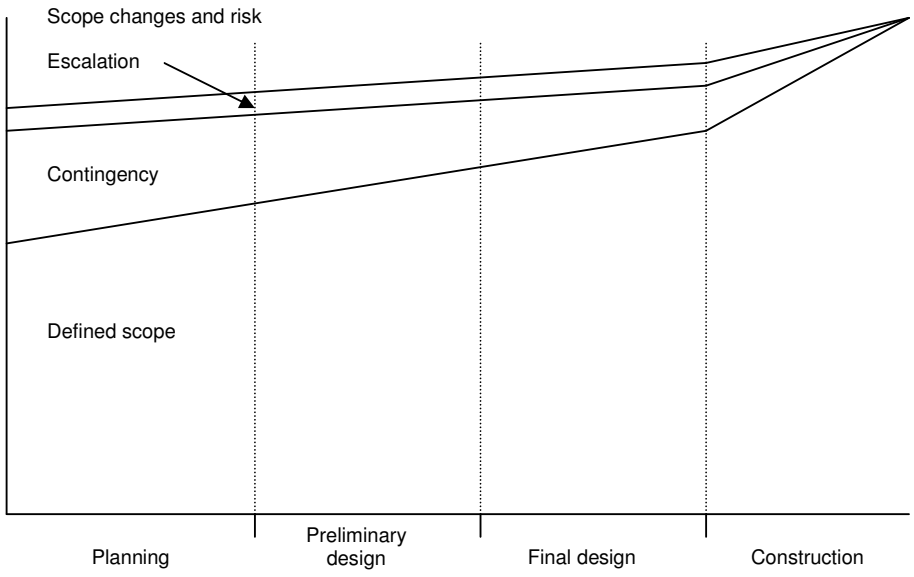

Figure 3.21 Change in construction variables during the course of a construction project

Source: Harbuck, 2007: EST.16.3

With speciality engineered equipment it is often likely that the quoted cost is not the final cost incurred by the project. Past project experience will lead the estimator to certain allowances for certain elements. Miscellaneous allowances may be included in an estimate in situations where a statistical correlation is more reliable than a detailed quantification, or where it is not economical to perform a detailed take-off. Percentage allowances are often included for such items. Material and/or labour costs routinely covered by such items include:

- percentage of hand excavation versus machine earthworks,
- formwork accessories,
- structural steel connection materials,
- bolts, gaskets, etc.,
- piping hangers, guides, etc.,
- miscellaneous welding operations, and
- hydro-testing and other testing operations.

Specific application of estimating allowances will depend on many considerations. For conceptual estimates, such as capacity factored estimates, allowances may not be required as the estimating methodology itself covers all scope and costs included in the project (Uppal, 2007: EST.03.9). Allowances are usually more applicable to semi-detailed and detailed estimates, with the cost value of allowances (or percentage costs) becoming less as the project definition increases. A specific allowance will usually depend on specific organisation estimating procedures and experiences (Dysert, 2006: EST.01.4).

Allowances are often included in an estimate to account for the predictable but indefinable costs associated with project scope. A way to include for these allowances is by adding a contingency amount to the estimate total (Burroughs & Juntima, 2004: EST.03.1). Such a contingency is required because estimating is not an exact science. The concept of contingency allowances is covered in more detail later in this study, but the basic essence of the contingency is illustrated in Figure 3.22 adopted from Noor and Tichacek (2004: RISK.04.2). With estimating in mind, it is however important to note some important allowances that the contingency does cater for and what it does not cater for. The contingency typically covers the following (Zhao, 2006: RISK.05.2; Singh Shiramizu & Gantam, 2007: 23 - 25):

- Errors and omissions in the estimating process.
- Variability associated with the quantification process.
- Design that may not be complete enough to determine final quantities at the time of estimate preparation.
- Some items that may defy precise quantification but are required to be estimated.
- Some items that need to be quantified that are generally computed by factored or other factored conceptual methods.
- Labour productivity variability.
- Labour availability skills and productivity that may vary from that originally assumed.
- The fact that there is no such thing as an “average” tradesman that installs every incremental quantity of an item at an “average” rate typically used in preparing the estimate.
- Weather which may vary from that assumed affecting labour productivity.
- Wage rate variability (Cohen, 1990: New York Times – 19 August).
- Wages that may vary from that assumed in the estimate due to inflationary reasons, changes in assumed crew mix, labour availability, and market conditions.

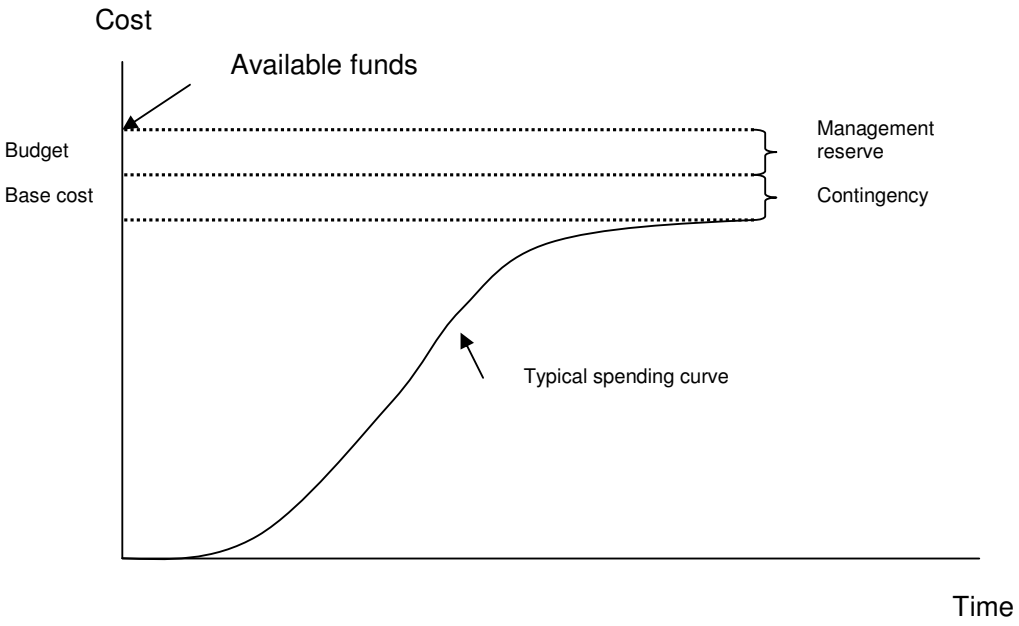

Figure 3.22 Relationship between the budget, contingency and management reserve

Source: Noor and Tichacek, 2004: RISK.04.2

- Inflation in material and equipment costs.
- Certain materials of construction that may be substituted from that assumed in the estimate.
- Changes in actual quantities that may change discount schedules from that assumed in the estimate.

Zhao (2006: RISK.05.2) points out that contingencies specifically exclude the following:

- Significant changes in scope.
- Major unexpected work stoppages (strikes, etc.)
- Acts of God.
- Excessive, unexpected inflation.
- Excessive, unexpected currency fluctuations.

6.5 Estimate accuracy

Estimate accuracy is described by Dysert (2006: EST.01.1) as follows:

> *"Accuracy is the degree to which a measurement or calculation varies to its actual value; thus estimating accuracy is an indication of the degree to which the final cost outcome of a project may vary from the single point value used as the estimated cost for the project."*

Figure 3.23 illustrates the concept of estimate accuracy in relation to the estimate's probability distribution. In the example the point estimate (the estimate before contingency) has a value of $1 million. Here the point estimate has a greater than 50% probability of being exceeded by the final cost of the project, and thus a positive amount of contingency would be added to reflect a 50% probability (or a 50% confidence level) of under-run or overrun of the expected final cost (Dysert, 2006: EST.01.1).

In this example the accuracy range is expressed as a percentage based on the point estimate. Should a contingency be added and the same variables would be applied, the situation will alter to the scenario sketched in Figure 3.24.

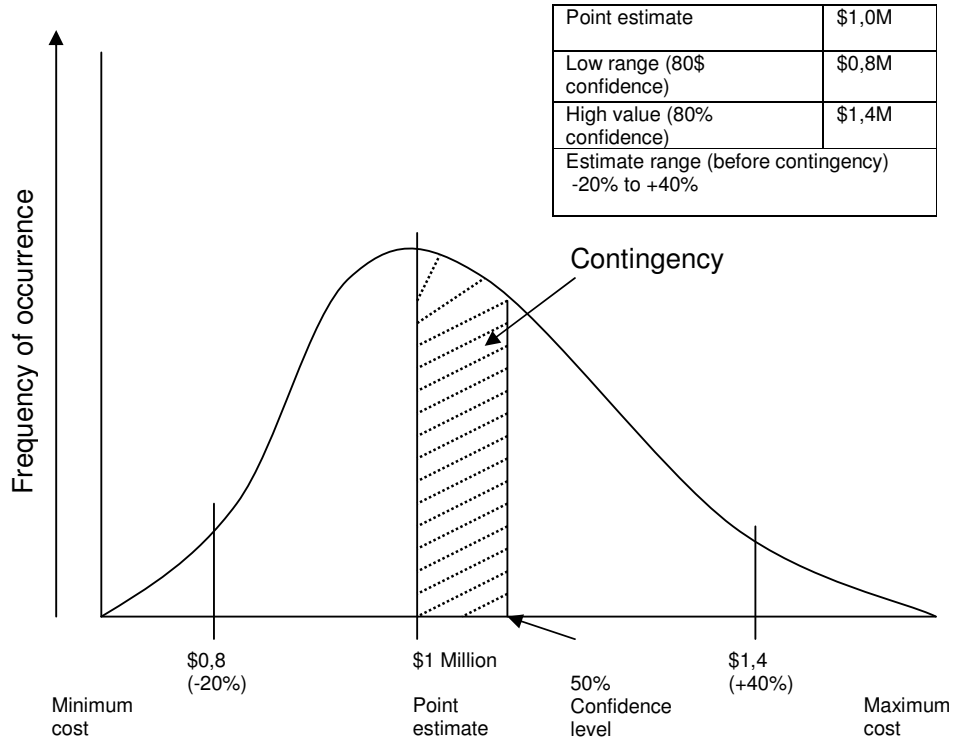

Figure 3.23 Estimate accuracy range around the point estimate

Source: Dysert, 2006: EST.01.1

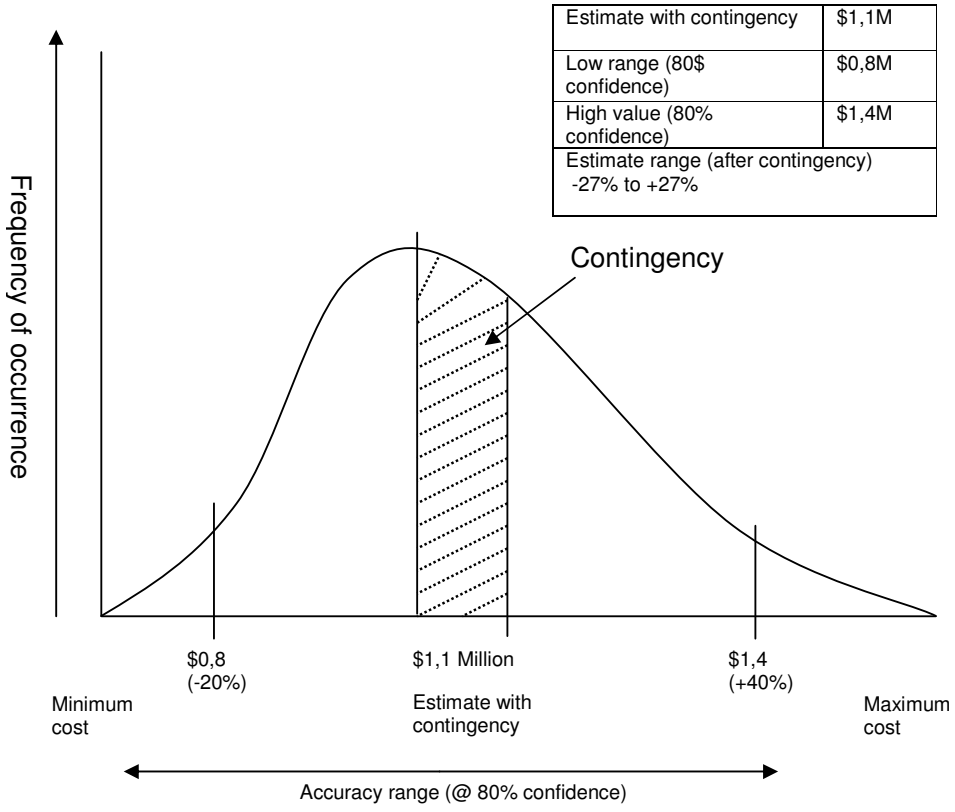

Figure 3.24 Estimate accuracy range around the estimate including contingency

Source: Dysert, 2006: EST.01.1

As should be expected, estimate accuracy tends to improve (i.e. the range of probable values narrows) as the level of project definition improves. Should this statement be compared to the AACE's classification of estimates, where increasing levels of project definition are associated with moving from Class 5 estimates to Class 4 estimates and eventually to a Class 1 estimate, accuracy can be directly linked to estimate classification. Figure 3.25 demonstrates this point.

Lukas (2006: EST.03.1) proposes four main factors that influence estimate accuracy making it a poor quality estimate. They are

- lack of scope definition,
- poor communication,
- unrealistic client expectations, and
- optimistic team members.

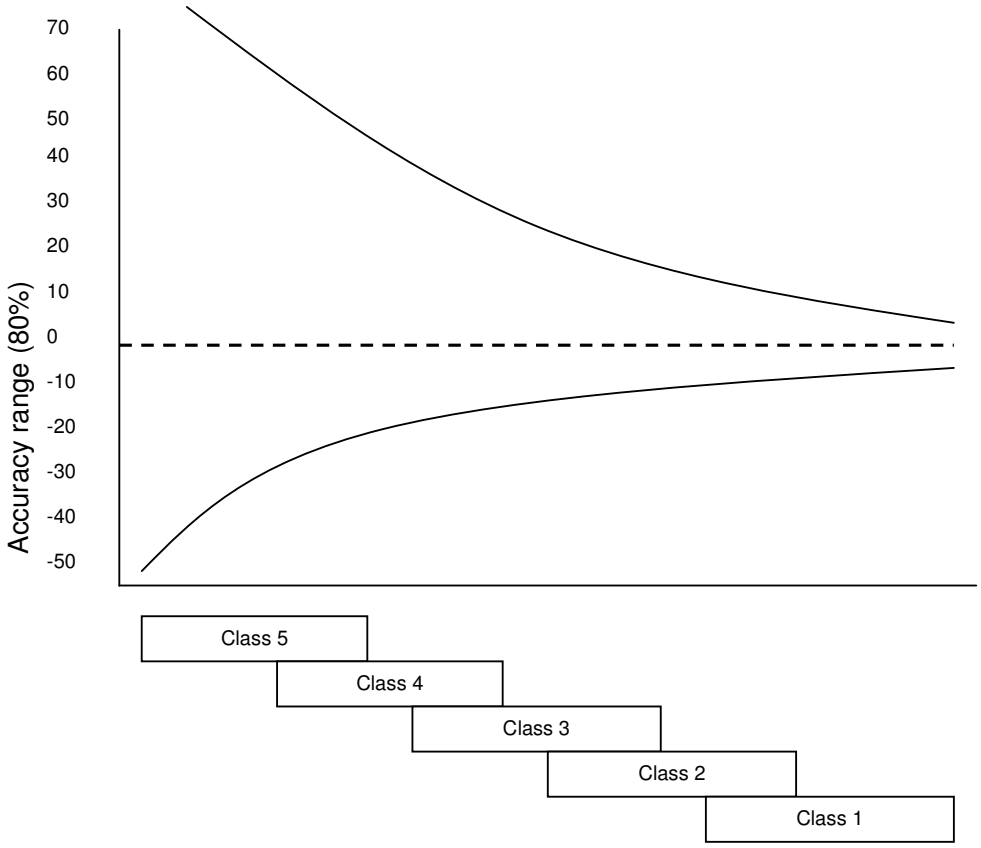

Figure 3.25 Estimate accuracy improves as the level of project definition improves

Source: Dysert, 2006: EST.01.1

Lukas (2006: EST.03.4) proposes the following tools to improve the accuracy of an estimate:

- Make sure the estimate matches the work breakdown structure.
- Do not allow over-optimistic persons to influence the estimator.
- Never estimate alone. Multiple opinions and views make for better estimates.
- Use risk analysis tools to help determine the potential estimate range and the appropriate amount of contingency to be included.
- Watch the level of precision used for the estimate total. Reflecting too exact a number implies a high level of precision, which probably does not exist within the estimate.
- Document assumptions and exclusions.

Lukas demonstrates in Figure 3.26 how the accuracy of the estimate increases as the estimate type changes to more detailed estimates as the project progress. This also ties-in with Dysert's illustration in Figure 3.25 that refers to the classification of the estimates.

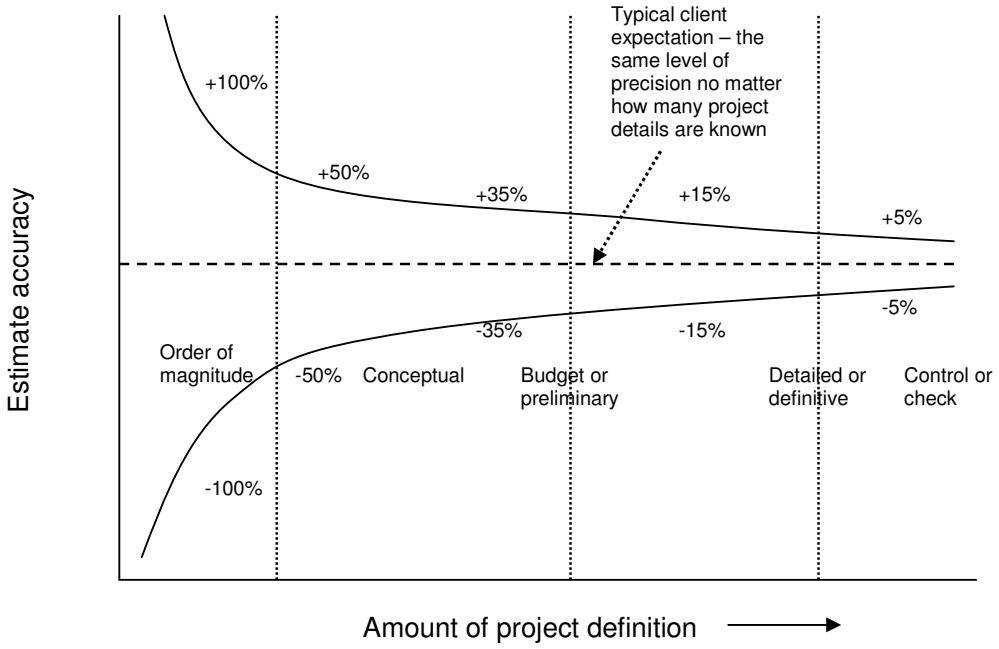

Figure 3.26 Estimate accuracy is dependent on the amount of project definition
Source: Lukas, 2006: EST.03.2

6.6 Structuring the estimate

The control structure for a project is the breakdown of the total work into manageable units or packages for the purpose of estimating and control of cost and schedule (Biffi, 2008: TCM.02.1). The structure will vary with the size and complexity of the project, as well as the reporting requirements (Bender, 2006: 3). The proper structuring of a project for control purposes contributes greatly to the effective implementation of project control procedures and the success of the project itself (Biffi, 2008: TCM.02.3).

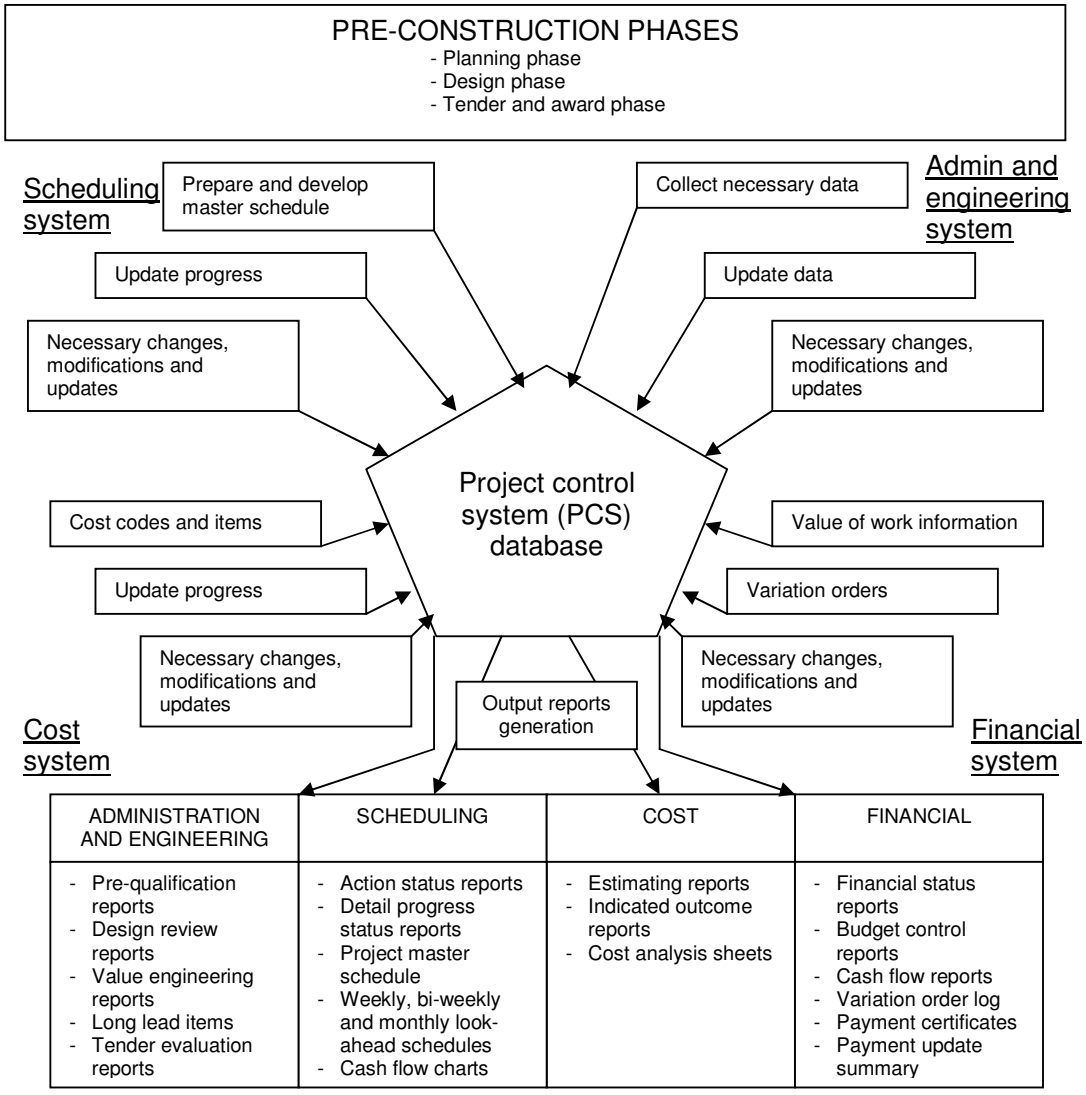

Figure 3.27 Project cost control system

Source: Al-Reshaid *et al.,* 2005: 353

The basics of project cost control have been discussed in Chapter 2 but Tang, Wang and Wang (2007: 1564) and Fleishman (2004b: CSC.09.2) comment on the importance of cost control and the proper structuring thereof and how it affects project success. Fleishman (2004b: CSC.09.2), Kern and Formoso (2006: 76), Dow (2004: 7) and Bredenhoeft (2005: EST.08.4) comment on the use of certain tools to perform cost control of which the proper structuring of the estimate is one. Al-Reshaid, Kartam, Tewari and Al-Bader (2005: 353) illustrate a typical project cost control flow diagram in Figure 3.27. It is important to note the structure and sequence of the project cost control system since the estimate will have to be built and expanded with this in mind.

To maintain some kind of order in the estimate (and later in project execution), it is necessary to segregate costs into various categories:

- Material and labour costs versus subcontracts.
- Direct costs versus indirect costs versus home office costs.
- Concrete versus structural steel versus piping versus other construction disciplines.

The control structure should be established as early as possible in the project life cycle (Biffi, 2008: TCM.02.1) because it will set the pattern for accumulation of project costs, and it should be used to form the basis for the structuring of the estimate. The process producing the project control structure, often known as work breakdown planning, is an ongoing process requiring updates as the scope of the project is refined during the project life cycle. The segregation of costs can be referred to as establishing the project "coding" structure, or more specifically, the "code of accounts".

Verveniotis (2008: PM.02.2) points out that larger projects normally will make use of a work breakdown structure (WBS) as well as resource breakdown structures (RBS) as components of the overall coding structure. Smaller projects will use a simpler code of accounts based on the disciplines or construction trades used in the project. The WBS and RBS are basic project management tools that define the project along activity levels that can be clearly identified, managed and controlled (Nachtmann & Al-Rifai, 2004: 225). Verveniotis (2008: PM.02.2) states that the WBS is the division of the project, for the purpose of management and control, into sub-projects according to its functional components. The WBS was discussed earlier in this chapter. Dysert (2004: 9.24) demonstrates the WBS and RBS in Figure 3.28 and Figure 3.29 respectively.

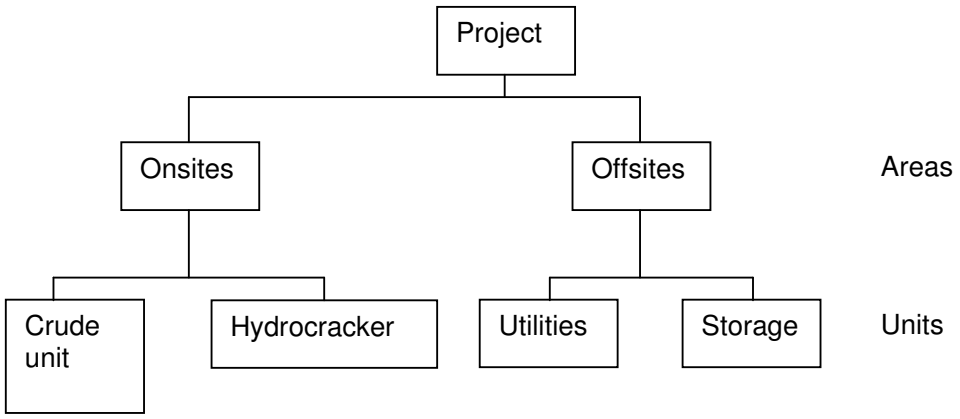

Figure 3.28 Simple work breakdown structure (WBS)
Source: Dysert, 2004: 9.24

Valle-Riestra (1983: 623) demonstrates a portion of a code-of-accounts in Table 3.5. In this case the 700 code series is reserved for the category of instrumentation. Most companies have their own standard code-of-accounts which can be adopted for each new project. In this case the code 722, for instance, represents control valves. These codes can be fairly detailed. Dysert (2004: 9.24), for instance, demonstrates how the labour for a concrete pouring exercise can be coded. He used this example: 01-02-C-2-003-1, which translates to (onsite-hydrocracker-construction-concrete-pour-labour). The coding structure must reflect the manner in which the project will be executed and the way in which costs can reasonably be expected to be collected (Verveniotis, 2008: PM.02.2). Estimates should therefore be structured to match the specific organisation's code-of-accounts (Chua & Godinot, 2006: 67).

6.7 Estimate review

The estimate is a prediction of the expected final cost of a proposed project. By its nature, an estimate is associated with uncertainty, and, therefore, is also associated with a probability of overrunning or under-running of the predicted cost (Dysert, 2004: 9.27). Leo and Knotowicz (2005: EST.05.1) point out that many companies do not necessarily rely on in-house estimating practices or services. Businesses are seeing their estimates being generated by a variety of sources. Some are done by centralised in-house estimating groups, others by groups at its international site or by a never-ending array of contractors (Hewitt, 2008: INT.05.1) Furthermore, estimates are generated in a variety of formats with a great degree of variability with regards to detail and clarity (Sonmez, 2005: EST.07.1).

The need for standardised estimating requirements to put a review process in place has long been realised. By doing this, the project team can review the project deliverables and estimated costs before the project is approved for execution. Estimates are checked to make sure that it is complete, accurate and generally ready to use as a project control baseline (Richards, 2006: EST.15.1).

Shirley and Banks (2007: EST.11.1) report on the estimate review process when involved in high-cost, high-risk projects. According to Ferrao (2004: 1) this refers to projects in excess of $100 million based on low technology levels. Experience shows that subjecting high-dollar cost estimates to a review process adds assurance that the overall estimate, assumptions, and the underlying data are verifiable and credible, at least at the point in time. Figure 3.30 shows how estimate reviews by management have altered initial estimated final costs. Shirley and Banks (2007: EST.11.1) conducted research on changes to estimates due to management reviews and the findings of four large size projects are shown in Figure 3.30.

6.7.1 The review process

A defined estimate review process makes good business sense and should be implemented in every estimating department (Leo & Knotowicz, 2005: EST.05.2). In order to conduct a review of a project estimate, certain project deliverables are requested from the estimator. Information with regards to the estimate should be available so that the reviewer can determine if the estimate is of sufficient quality to satisfy its independent purpose. A written “base of estimate” is a critical component of a cost estimate because it highlights what the estimate does or does not contain. Without this information, it becomes difficult to perform change management to control costs (Arain & Pheng, 2005: 4). Basis information needs to include the following:

- General overview: Provides a brief overall description of the facility or project.
- Scope description: This section should provide greater detail about each major segment of the project
- Execution strategy: This describes the general construction philosophy to be utilised for the project.
- Allowances: The level and types of allowances used in the estimate should be noted.

- Exclusions: What is excluded from the estimate is just as important as what is included.
- Assumptions: Any other assumptions not identified elsewhere in the basis should be noted.
- Exceptions: Any pre-determined project deliverable not available will be recorded.
- Contingency: The amount of contingency included and the method utilised to determine the contingency should be documented.
- Reference documents: A list of the information used to prepare the estimate.

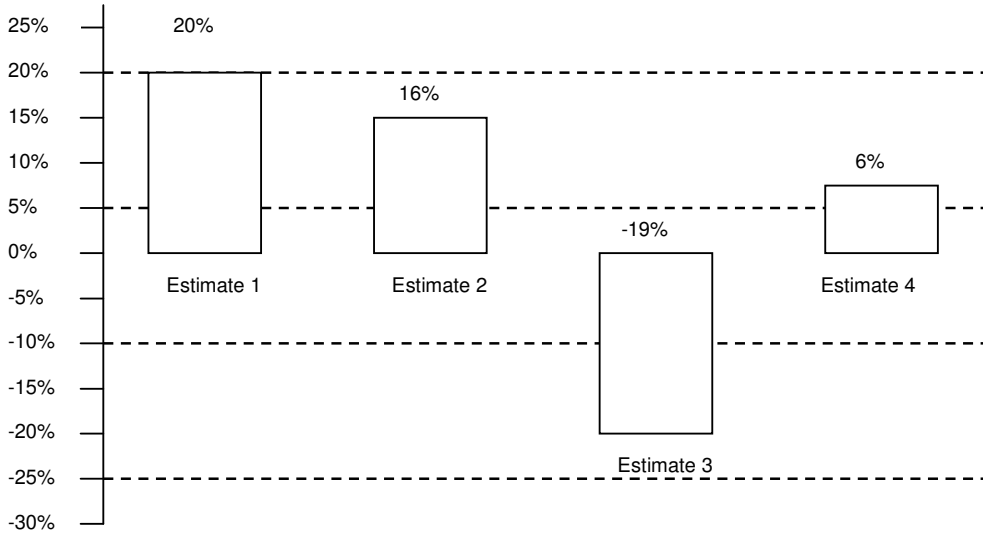

Figure 3.30 Percent change in estimates due to management reviews
Source: Shirley and Banks, 2007: EST.11.1

Jambhekar and Weeks (2007: OWN.02.3) report on the estimate review process and in particular on the challenges it poses to the project team. Figure 3.31 demonstrates how the development of a schedule and cost estimate is related to the steps taken by the owner to complete the estimate review.

To conduct the review an understandable project estimate utilising an agreed upon code of account type structure is necessary. Leo and Knotowicz (2005: EST.05.2) refer to the following items that can be used to easily identify and benchmark costs:

- Administration/home office costs.
- Engineering costs.

- Major equipment costs.
- Installation costs.
- Investigation costs.
- Software costs.
- Debug costs.

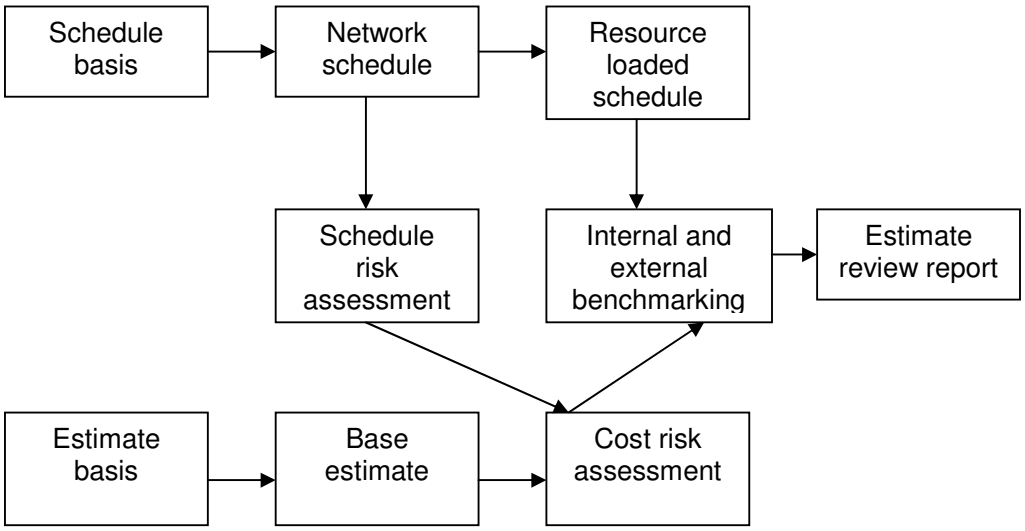

Figure 3.31 Estimate review process for a full-funding decision
Source: Jambhekar and Weeks, 2007: OWN.02.3

Organising estimates in this kind of systematic procedure provides a means for identifying costs incurred in the execution of the project. Furthermore, this method allows estimates to be benchmarked against actual costs of similar type projects during the review process. Bredenhoeft (2005: EST.08.5) illustrates the estimate-review (validate)-approval process by means of a flow diagram in Figure 3.32.

To understand the estimate content, the reviewer will need a list of all relevant drawings, sketches, specifications, equipment lists, design basis of estimate and engineering/design costs (Bain, 2008: Financial Mail – 12 September). It is important to understand how the project contingency was determined. Did the team perform a formal risk analysis on the project to determine the probability of overrunning specified estimate values? Contingencies are too often added to an estimate by a “gut feel” approach rather than an approved statistical methodology. More information on contingency allowances will follow. Benchmark evaluations comparing key project

estimate ratios and factors against actual project histories need to be presented and reviewed.

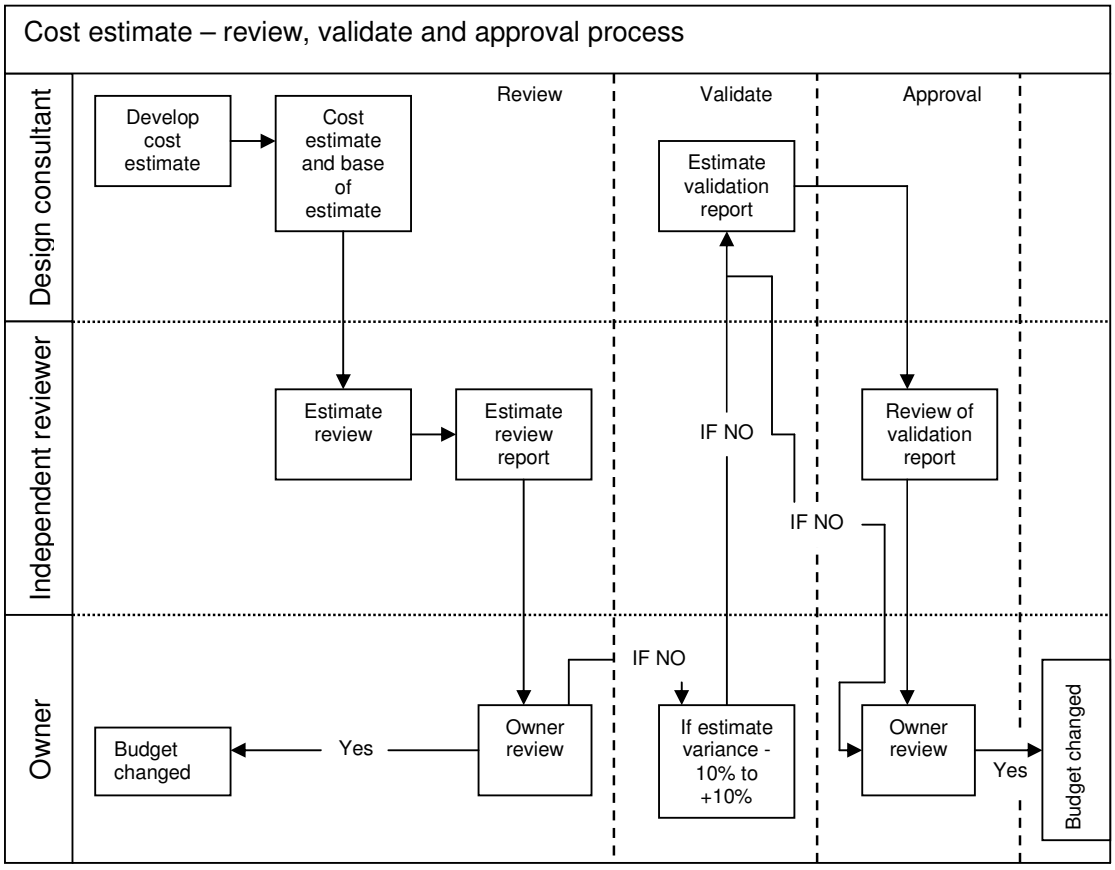

Figure 3.32 Cost estimate-review (validate)-approval process

Source: Bredenhoeft, 2005: EST.08.5

6.7.2 Conducting the actual review

Estimates are presented in different ways by various parties. Some estimates have too little information and some estimates too much. In an effort to provide a degree of estimate clarity and consistency, a series of tools can be used.

6.7.2.1 Estimate summary worksheet

The first tool to assist the estimate reviewer is the estimate summary worksheet that can be viewed in Addendum B (Leo & Knotowicz, 2005: EST.05.2). Cost information is summarised on a relatively high level into a code of accounts format. This allows the estimate reviewer to easily see cost totals for items such as engineering, purchases and constructions and how they relate to the total project cost. The cost of procurement

should relate to the engineering and installation costs. The summary level report will enable the review process to benchmark the estimate against other similar estimates.

6.7.2.2 Project team “basis of estimate” report

As previously mentioned, the “basis of estimate” report is critical and needs to be provided in order to understand the cost basis of the estimate. This report needs to highlight what the estimate does and does not contain. Too often projects get into trouble because of incorrect assumptions as to what the estimate costs represent. This document basically puts the amounts of the estimate into words (Jambhekar & Weeks, 2007: OWN.02.3).

6.7.2.3 Cost estimate review and benchmarking report

This report is the basis for the actual review of the estimate. The main contents of what should be included in such a report are clear scope definition, risk analysis and benchmarking. Scope definition for conceptual estimates is different from that of semi-detailed and detailed estimates (Leo & Knotowicz, 2005: EST.05.2). A detailed estimate that is loaded with cost allowances would require a great deal of explanation. Exceptions to the scope should be reviewed and suggestions for possible improvements should be offered. Any technical deliverables that are not available should be noted. Major mechanical equipment, electrical and instrumentation components need to be double checked and any adjustments to allowances and contingencies must also be double checked. Benchmark ratios for similar projects will be used to compare with the estimate. Through the use of a defined estimate review process, the estimator can ensure that high quality estimates are prepared that will support the decision-making process for capital projects.

6.7.3 Estimate review challenges

Chuong (2007: EST.07.3) comments that in the current dynamic global market, cost engineering professionals face unprecedented challenges in cost estimation. Similar challenges are encountered during project estimate review (Creech, 2005: PM.16.1). These challenges include the following:

- High crude oil prices affecting the capital project market.
- Increase in material prices (steel, copper, etc.)

- Increase in day rates of offshore vessels.
- Volatility in foreign currency exchange.
- Local content requirements.
- Limited contractor pool in certain areas.

6.8 Engineering/design review

Shah *et al.,* (1996: 348) describe the importance of engineering history. This history can be very helpful when pricing engineering projects and can also be of help when assessing the estimated cost for a future project (Struts & Griffis, 2005b: 56). The main purpose of the engineering review is to evaluate the scope of work. The first objective of such a review is to make sure that the engineering deliverables have not been misunderstood and that the plant is designed to meet the client's objectives (Baskaran, Ham & Lei, 2006:1 170). It is especially when late changes to the engineering drawings have occurred that the estimator should make sure that the estimate is based on the latest drawing revisions (Kirkham, 2005: 9).

The cost of mechanical equipment will have a major influence on the equipment list used. This is also an important consideration as equipment prices are in most cases the driving factor of plant costs (Maples, Greco, Heady & Tanner, 2005: DEV.05.1). Any queries that the estimator has regarding the project scope have been asked by this stage, but the estimator can clarify any specification or drawing details during this review (Whiteside, 2005: EST.04.2).

6.9 Estimating resources

Reliable estimate preparation depends on good information and in particular on good historical information (Marx, 2004: 2). Dysert (2004: 9.32) describes some of the additional information, besides the engineering and design information, needed to quantify the scope of the project:

- Conceptual estimating factors.
- Material cost and pricing information.
- Labour work hour charts and information.
- Labour productivity information.
- Labour wage rates, composite crew mixes, etc.

- Other estimating factors and information.

Normally estimating guidelines and procedure manuals will be used to promote standard estimating methods and procedures. In-house cost history manuals will provide historical cost data for completed projects (Musgrove, 2008: EST.07.2). Engineering and design manuals will be used to identify specific materials of construction, and all related labour operations required to complete the scope of work.

Completed projects should be documented by means of a post-mortem final job report covering everything about the project from design considerations to construction execution strategy and to cost summaries (Humphreys, 2007: 10). Estimators continually rely on historical project information and cost data in the preparation of new estimates. Together with this information, the estimator will also rely on computer software (either in-house developed or from commercial sources). Karshenas (2007: IT.06.1) and Masmoudi *et al.,* (2005: 299) demonstrate how specialised computer software can be integrated into existing design packages to assist the estimator while Richards (2005: EST.12.1) cautions estimators on the use of computers in estimating even though it can be of great assistance. Inconsiderate use of formulas or the lack of appropriate formulas can lead to gross mistakes.

7.0 SUMMARY

Cost estimating is by no means an exact science. The estimate is a prediction of the expected final cost of a proposed project. By its nature, an estimate is associated with uncertainty and therefore is also associated with a probability of overrunning or under-running of the predicted cost.

To perform an estimate the estimator should be well versed in the different types of estimates and their uses. He should understand the scope of work and should ask the right questions when it comes to scope clarification. Scope definition should in fact be considered the most important aspect of estimate success and the estimator must make sure that enough time is spent on understanding the scope to have sufficient information to rewrite the scope of work in terms of cost.

Even though the scope of work is a major component in the estimate process, there are several other factors influencing the estimate accuracy (Schottlander, 2006: EST.17.2). Whether they are external or internal factors, these items should be

reviewed and allowances should be made accordingly. Each project differs and certain factors which might not have had a significant influence on previous projects may now be important and carry major costs. All estimating tools are therefore useful to some or other extent.

Estimating principles and procedures will have to be followed in order to proof the hypothesis of this study. Although detailed estimates provide a more accurate estimate for management to use, there is not always time to perform such an estimate or the information required to do such an estimate is not yet available at that stage of the project. This is especially true in the case of financial forecasting. Well-balanced conceptual estimating methodologies will therefore be more useful when evaluating financial forecasts.

Conceptual estimates are typically used for low level accuracy estimates to assist management in early stage decision-making. These estimates are often referred to as “order-of-magnitude” or OOM estimates in reference to their typical wide range of estimating accuracy. The following chapter will investigate the spirit of the conceptual estimate and will discuss the methodologies and uses of these estimates. Specific focus will be placed on factored estimates, as this will be the estimate type used in proving the hypothesis.

CHAPTER 4

CONCEPTUAL COST ESTIMATING METHODOLOGY

1.0 INTRODUCTION

Kinney and Soubiran (2004: EST.15.1) state that it is accepted practice throughout the petrochemical industry to make important business and design decisions early in the evolution of the project. Engineering and construction professionals are under increasing pressure to build more efficient chemical process plants at lower costs (Uher, 1996: 85). To that end, significant demand exists for cost professionals to develop a work method designed to proactively support increased consistency and accuracy in the development of conceptual cost estimates much earlier in the evolution of a project. Conceptual estimates are also referred to as “Order-of-Magnitude” estimates and usually take form in a Class 4 or 5 estimate. Refer to Chapter 3 for more information on estimate classification.

The importance of early cost establishment of project costs has been discussed earlier in this study. The result is that the ultimate costs of a project are influenced by those early decisions made during the process-design stage of a project (Abi-Karam, 2004b: PM.04.2). To optimise those early decisions, cost estimates should be developed in the early stages of design evolution (Ahcom, Uddin & Shash, 2006: EST.26.2). The conceptual estimate is ideally intended to reflect the full impact of those early decisions (Anonymous, 2008h: 21).

While realising that the method of creating a conceptual estimate is an art and not an exact science, the accuracy and completeness of a conceptual estimate becomes crucial to making cost-effective decisions earlier in the development stages of a project (Li, Shen & Love, 2005: 440). Kinney and Soubiran (2004: EST.15.1) indicate that when 80% of costs are committed, only a limited portion of the engineering is completed.

Kinney and Soubiran (2004: EST.15.1) indicate that the conceptual estimate supports budget and business development and resource planning by:

- Establishing a budget and cash flow for funding decisions, screenings and approvals.

- Optimising resource utilisation.

Serpell (2005: EST.13.1) indicated that conceptual estimates support engineering and design development by:

- Identifying completeness of process design and clarifying the project scope.
- Providing the basis for value engineering, feasibility studies and design changes.
- Developing design and construction schedules.
- Highlighting process design decisions and associated risks.

Conceptual estimates are generally based on little project information, for instance engineering deliverables, thus subjecting them to a wide range of estimate accuracy. According to Serpell (2005: EST.13.1), their accuracy can depend on several factors, including the level of project definition, the quality of the past historical cost data (Pickett & Elliott, 2007: EST.02.1) in development of the factors and algorithms, as well as the judgment and experience of the estimator. These limitations should be recognised in using conceptual estimating methods. Nonetheless, there can be cases where conceptual estimates can be very reliable, especially in estimating repeat projects (Sonmez, 2004: 677). Generally, the emphasis with conceptual estimating is not on detailed accuracy, but on obtaining a reasonable cost estimate of sufficient accuracy to ensure that the results are meaningful for management to make the decision at hand (Dysert, 2008: EST.03.1).

The development of the initial conceptual estimate is only one step of many in expanding an interactive process of communicating the cost, scope, and schedule risks inherent in early process designs (Serpell, 2005: EST.13.1). Even though the quality and level of design definition developed during the conceptual stage of design is sufficiently accurate for feasibility studies and alternative analysis, it is not sufficiently accurate to make full funding decisions and investments without incurring substantially more risk than most corporations are willing to accept (Humphreys, 2004).

2.0 ROADMAP TO CONCEPTUAL COSTS ESTIMATING

The conceptual estimating process is composed of a multitude of information formats. Kinney and Soubiran (2004: EST.15.1) describe six steps towards successful conceptual estimating. These steps are as follows:

- Develop an estimating plan.
- Develop major equipment costs (MEC).
- Apply factored costs.
- Develop quantified costs.
- Develop indirect costs.
- Analyse risks, apply contingency and finalise estimate.

Failure to plan the estimate almost always results in failure to communicate many of the critical aspects of the design that are revealed during the development of the conceptual estimate (Termini, 2003: 47). Planning of the conceptual estimate (Step 1) is illustrated in Figure 4.1.

Figure 4.2 demonstrates Step 2 of the process for the pricing of major process equipment. The purchase cost of many types of major process equipment can be estimated at the conceptual stage by using historical actual costs (Kaka, 1999: 256). Early in the conceptual stages a list of major process equipment is developed from the Process Flow Diagrams (PFD's) (Uppal, 2007: EST.03.2). Normally the equipment list consists of four line items which include a description, design capacity, material of construction and design temperature and pressure (Louw, 2002: 52).

An internal database of previous purchased costs is useful as a tool to validate prices from other sources (Shah *et al.,* 1996: 347). When possible, do not make use of vendor prices too early in the project. Early quotes are usually less accurate than historically based costs, but can be useful in assessing market trends (Abi-Karam, 2004: DEV.04.1).

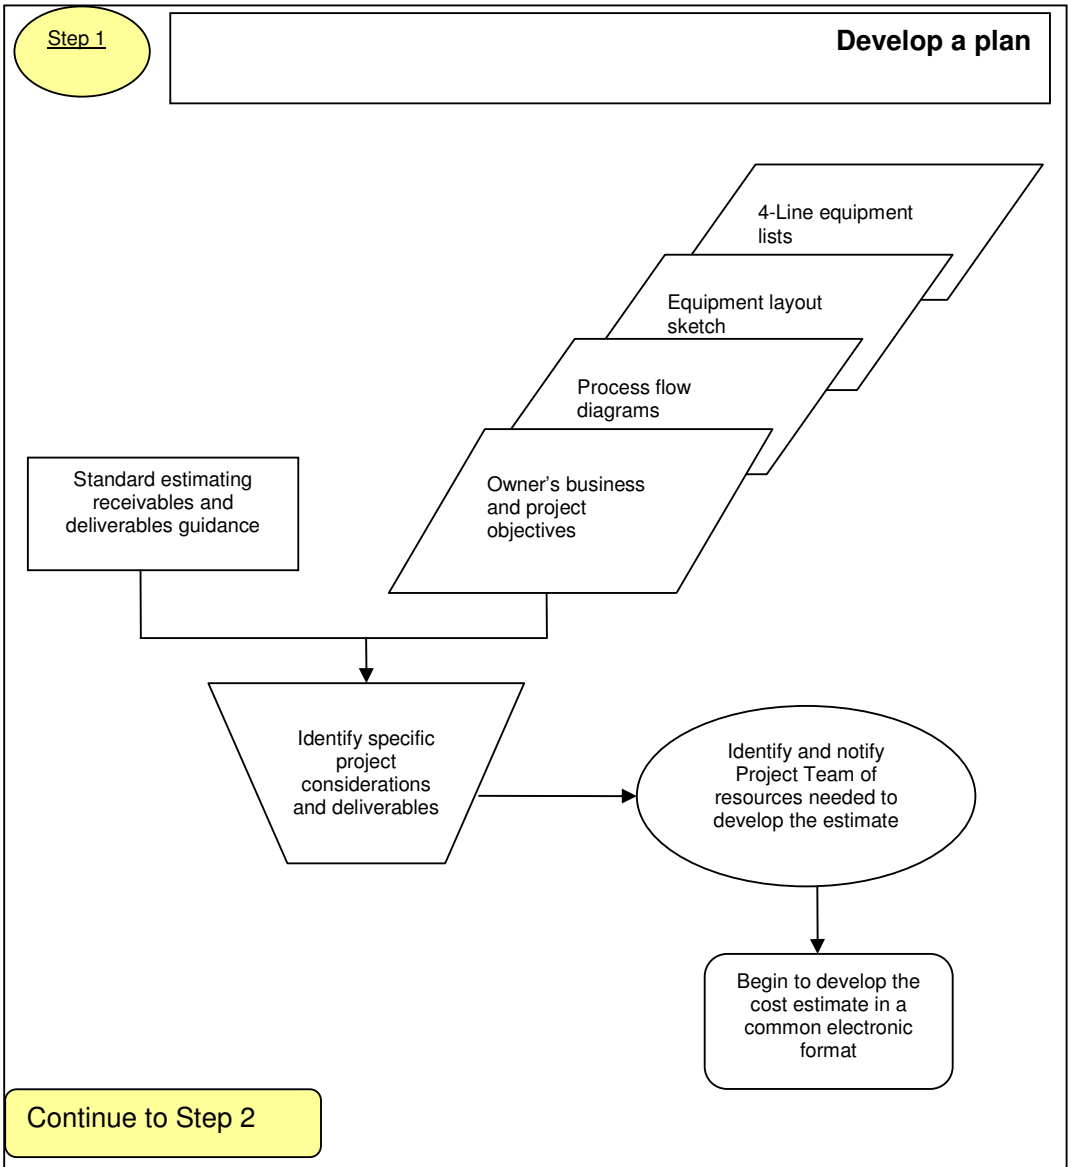

Figure 4.1: Step 1 in the conceptual estimate process: Develop a plan

Source: Kinney and Soubiran, 2004: EST.15.4

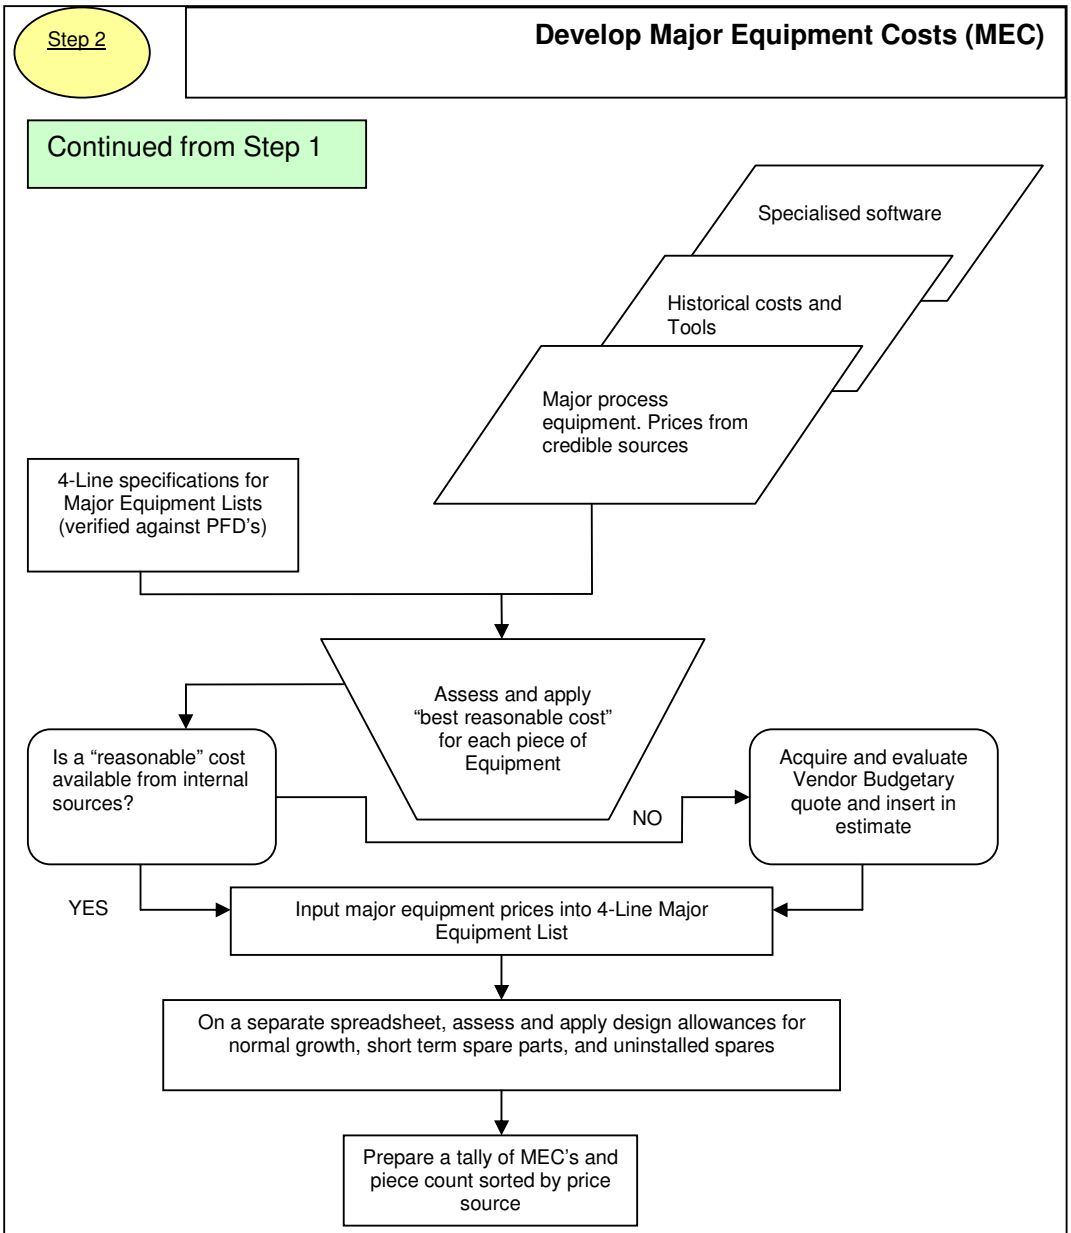

Figure 4.2: Step 2 in the conceptual estimate process: Develop Major Equipment Costs (MEC)

Source: Kinney and Soubiran, 2004: EST.15.5

Figure 4.3 illustrates the development of the construction and site (field) installation elements of the "total installed cost" for the major process equipment which will be Step 3 – the application of factored costs. "MEC factors" are cost multipliers applied to the Major Equipment Costs (MEC) to obtain a Total Installed Cost (TIC) (Noor, Grumo, Kniskern & Kopach, 2006: OWN.05.2). MEC factors consist of the cost for bulk commodities (materials), direct field labour to install the equipment and the bulks, and indirect cost such as engineering, project staffing and construction equipment. The MEC factors can range from a multiplier as little as 2 for skid mounted equipment to a multiplier of 20 for very small bench-top scale complex equipment.

Musgrove (2008: EST.07.2) points out that the most accurate cost factors are cost models created by collecting and using historical cost data. These can be accurate to ± 10% if developed and applied properly. Table 4.1 shows a table of commonly used MEC factors and breakdowns. These factors are limited to In-Side Battery Limits (ISBL) and do not capture any Outside Battery Limits (OSBL) cost for infrastructure or utilities. Normally ISBL includes concrete foundations, structural supports at grade (not elevated), pipe to the nearest header, local instruments and controls, cabling to the nearest junction box and insulation (Kinney & Gauche, 2006: EST.14.1). To properly use factors it is important to have a clear understanding of what is included in the factors (Kapetanios & Marcellino, 2009: 208). Factors can be impacted on equipment size (capacity), material of construction, pre-fabrication, market conditions, and horizontal and vertical layout.

Figure 4.4 illustrates the fourth step in conceptual estimating – the development of non-process and infrastructure elements of a project. OSBL cost factors, at the conceptual stage, are usually historically based costs of similarly constructed plants. However, OSBL costs are impacted by pre-investments in existing infrastructure and utilities.

For a higher degree of accuracy, the OSBL scope should be conceptually quantified (Serpell, 2005: EST.13.5). Table 4.2 illustrates this statement. This table shows "assemblies" rather than detailed single line items. The design in the OSBL area normally changes quite significantly in the conceptual stage of the project. It is therefore not wise to prepare detailed estimates of the OSBL area at this stage. OSBL typically includes pipe racks outside the process area for vertical and horizontal separation between the production processes, control building and equipment isolated from production processes, treatment systems, packaged systems, etc. (Kinney & Gauche, 2006: EST.14.1). Budgetary quotes can be used on OSBL assemblies, but

only with caution. Budgetary quotes are never totally complete. The estimate should be adjusted to allow for these incomplete items.

Major Process Equipment Cost Factors for Bulk Commodities and Direct Field Labour (Process capitalised costs only)

Major Equipment Item	Range of Factors	Suggested Factors	(CS) MEC	Bulks	DFL
AIR – Air Coolers	1.7 – 2.1	1.70	1.00	0.96	0.74
ATR - Agitators	1.1 – 2.0	1.10	1.00	0.62	0.48
BLT – Belt Conveyors	1.7 – 2.2	1.70	1.00	0.96	0.74
ATR - Blenders	1.6 – 2.0	1.60	1.00	0.91	0.69
BLO – Blowers & Fans	1.1 – 2.2	1.10	1.00	0.62	0.48
BOI – Boilers (Design & Fabricate)	0.75 – 2.3	0.90	1.00	0.51	0.39
BKL – Bucket elevators	1.8 – 2.2	1.80	1.00	1.02	0.78
BUL – Bullets (Pressure)	0.9 – 2.5	0.90	1.00	0.51	0.39
CNT – Centrifuge	1.2 – 1.9	1.50	1.00	0.85	0.65
COL – Columns	1.3 – 2.6	2.00	1.00	0.74	0.56
CMA – Compressors - Air	1.2 – 2.3	1.30	1.00	0.74	0.56
CMR – Compressors - Centrifugal	0.9 – 2.1	1.10	1.00	0.62	0.48
CTP – Cooling Tower Package	0.6 – 3.9	0.91	1.00	0.38	0.53
CRU – Crushers and Mills	1.6 – 2.1	1.60	1.00	0.91	0.69
CYC – Cyclones	1.5 – 2.1	1.50	1.00	0.85	0.65
DEM – Demineralisers (Ion exchange)	1.3	1.30	1.00	0.74	0.56

The design and project execution costs are captured in the fifth step on the roadmap to conceptual estimating. This is illustrated in Figure 4.5. At this stage an estimate basis document should be developed. This document should include the following information:

- A brief scope statement.
- The 50/50 estimate and range.
- A single cost summary page.
- A list of major exclusions and assumptions.
- A list of allowances for known but unquantified and/or undefined scope.
- Project design and execution concerns.
- Identify project resources used to create the estimate (documents and people).
- MEC price source/analysis.
- Cost basis (factors used) with adjustments for time and plant location.

- Critical and major schedule milestone dates.
- Reconciliations to previous estimates.
- Reviews and validations of the cost estimate.

A staffing plan is required and should be based on a list of deliverables and hours with associated rates. Engineering costs are typically broken down as “Expense” or “Capital” costs and can be included in the conceptual cost estimate using typically industry benchmarks if better historically based cost information is not available.

Probably the most important step in the roadmap to conceptual estimating is the assessment of project risks, review cycles and the finalisation of the cost estimate (Singh *et al.,* 2007: 20). Figure 4.6 illustrates this step. An important part of this step is the development of an undefined sum of money, or contingency amount, to be included in the estimate as a risk buffer (Gunham & Arditi, 2007: 495). More detail on contingency development will follow later in this study.

At this stage of the discussion on conceptual estimates it should, however, be noted that the contingency should only be applied for “changes that experience shows will likely be required”. It is for known, non-quantifiable, but statistically proven unknowns and uncertainties (known unknowns). Most importantly, the contingency is not a tool for capturing incomplete or inadequate scope (Burroughs & Juntima, 2004: EST.03.2).

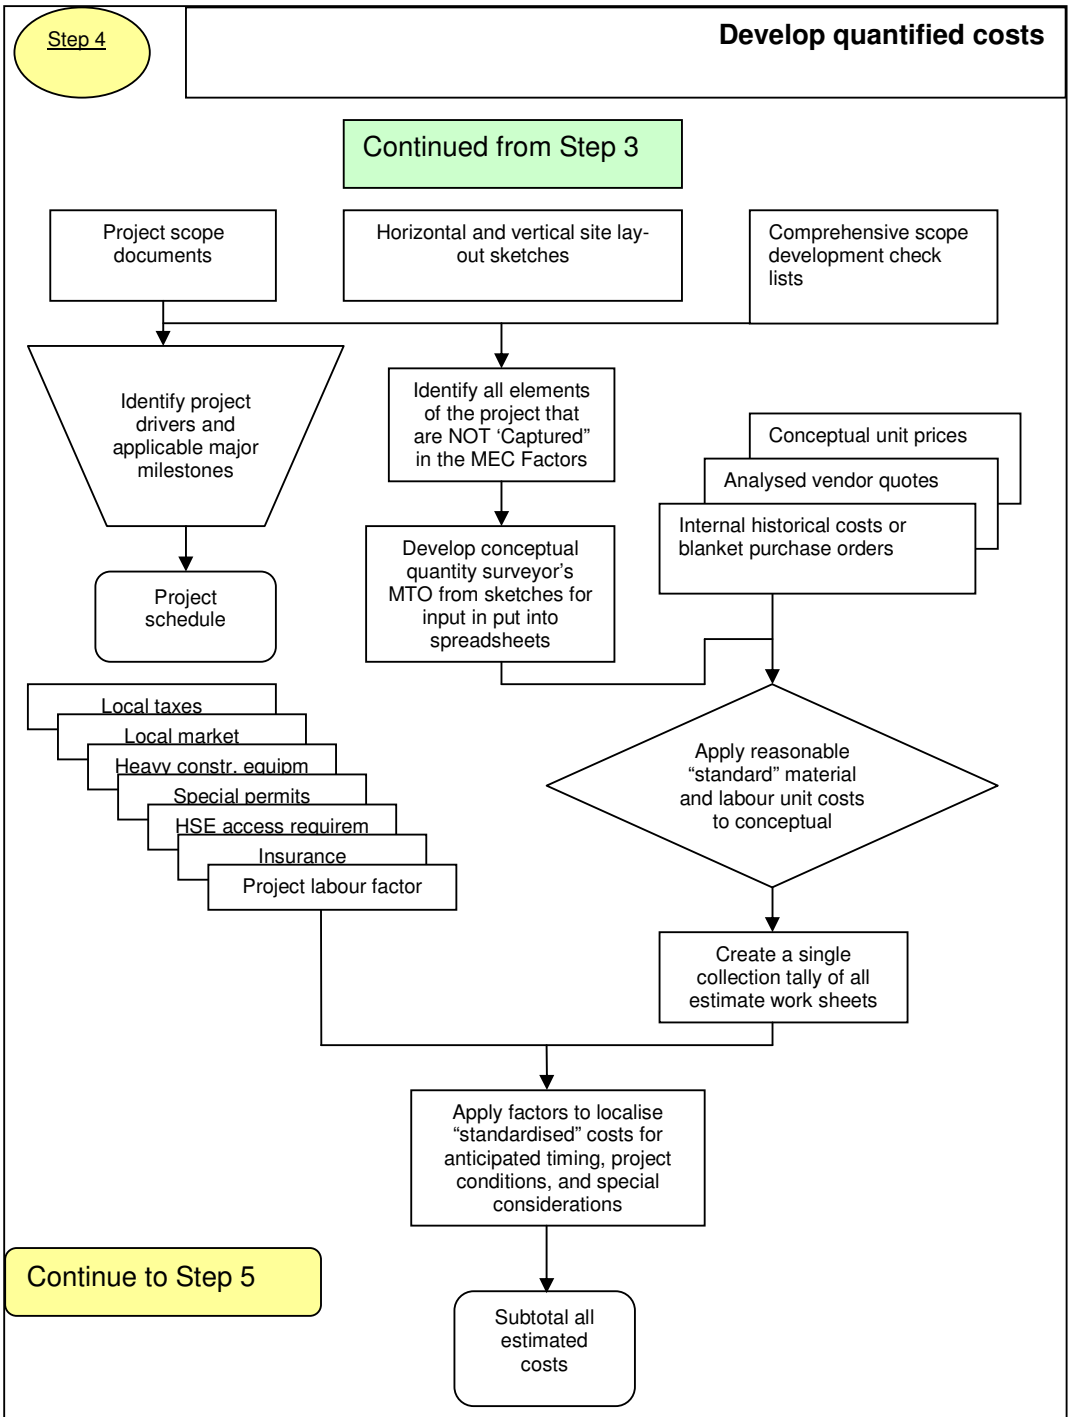

Figure 4.4 Step 4 in the conceptual estimate process: Develop quantified costs

Source: Kinney and Soubiran, 2004: EST.15.9

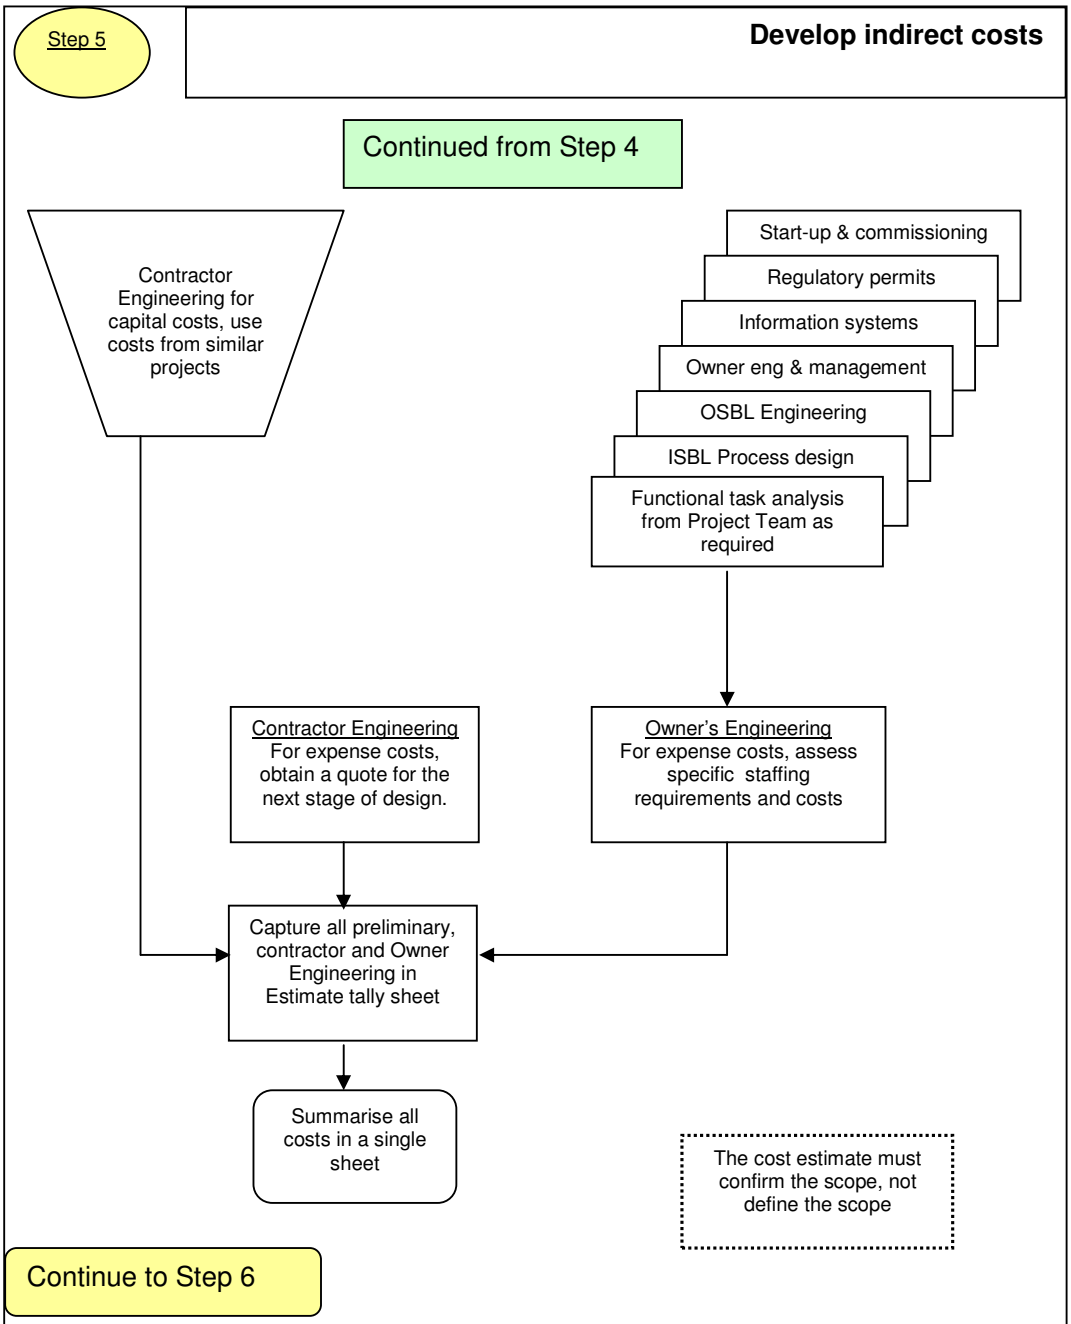

Figure 4.5 Step 5 in the conceptual estimate process: Develop indirect costs

Source: Kinney and Soubiran, 2004: EST.15.10

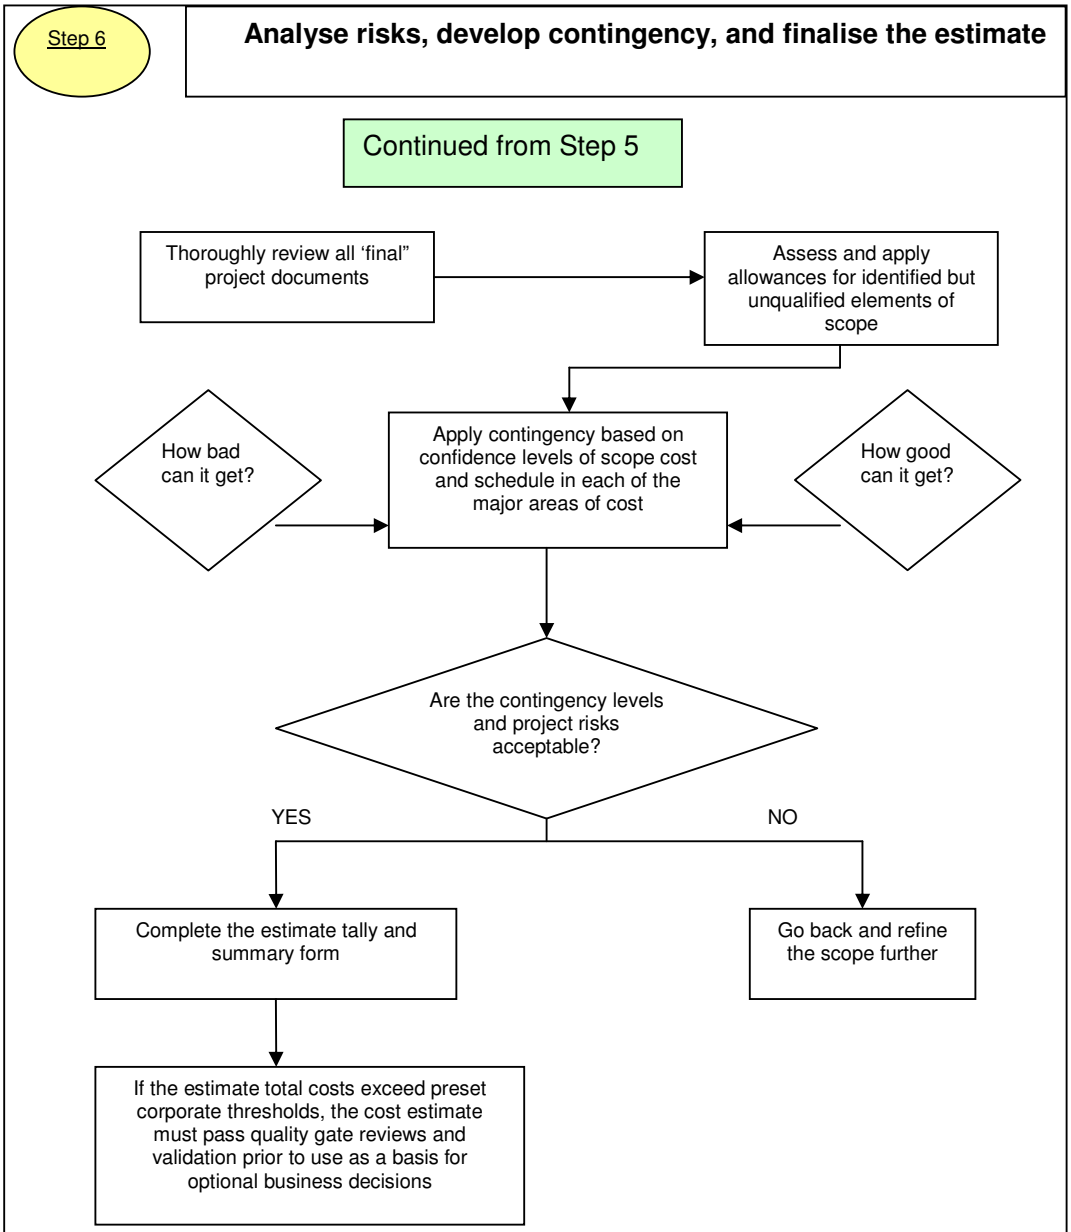

Figure 4.6 Step 6 in the conceptual estimate process: Analyse risks, develop contingency, and finalise the estimate

Source: Kinney and Soubiran, 2004: EST.15.11

Noor and Tichacek (2004: RISK.04.1) state that some of the contingency predictability issues to consider will include the following:

- Normally engineering design at conceptual stage includes for first pass equipment sizing at 100% and not 100% plus final equipment duty and sizing.
- Design detail assumptions and design allowances.
- Rework (identified as design and field change orders occur on every project).
- Complexity of design, particularly for new technology or even retrofits.
- Methods, motivations and biases during the development of the scope and the cost estimate.
- Inaccuracies, omissions and misunderstandings of the early engineered design.
- Mistakes using a complex set of calculations
- Accuracy of historically based "actual" cost data used in the estimate.
- Planning, project execution and contracting strategies.
- Mistakes in material take-offs, waste allowances, theft, etc.
- Financial stability of owner/contractor.
- Weather delays, unplanned bonuses, etc.

2.1 Project escalation

In Chapter 6 of this study project escalation and how it influences the project's total estimated cost is discussed. Hollmann and Dysert (2007: EST.01.2) mention that it is important to note that price escalation can be seen as a project risk and should be included in the estimate. According to Butts (2007: EST.08.1), the determining of the escalation percentage to an estimate is often the subject of fierce debate. He goes on to say that cost increases are determined by dynamic relationships between many factors, including acts of nature, interest rates, oil prices, global commodity markets, wars, wage rates, and the overall health of the economy, as well as supply and demand for the required goods or services. Morris and Wilson (2006: CSC.06.2) and Hollmann and Dysert (2008: EST.08.2) note similar findings. Accurately forecasting escalation rates can play a pivotal role in determining project profitability or project viability – especially for large multi-year construction projects (Hollmann & Dysert, 2007: EST.01.1). The estimator must predict the cost of future goods or services that

must be procured in the future, perhaps many years from now (Jackson, 2008: INT.S01.2).

Project start date	**Duration days**	**Index at start**	**Index at end**
2001-04-17	500	100.0	120.0
Percent of duration between project approval and ready for operation. Construction starts at 35%.	Day number	Index	Payment dates
0.0	0.0	100.0	2001-04-17
20.0	90.9	103.6	2001-07-16
35.0	159.1	106.4	2001-09-23
37.0	168.2	106.7	2001-10-02
38.8	176.1	107.0	2001-10-10
40.0	181.8	107.3	2001-10-15
42.5	193.2	107.7	2001-10-27
43.0	195.5	107.8	2001-10-29
44.0	200.0	108.0	2001-11-03
45.0	204.5	108.2	2001-11-07
46.3	210.2	108.4	2001-11-13
48.0	218.2	108.7	2001-11-21
50.0	227.3	109.1	2001-11-30

Table 4.3: Escalation index increase as time goes by
Source: Louw, 2002: 99

Escalation is directly associated with time (Butts, 2007: EST.08.1). The longer any contractor stays on site because of factors beyond his control, the greater the risk to the employer (Touran & Lopez, 2006: 853). Table 4.3 shows an example of how the escalation index increases as time goes by. Should the information in this table be illustrated on a cumulative graph, the result will look similar to the graph shown in Figure 4.7.

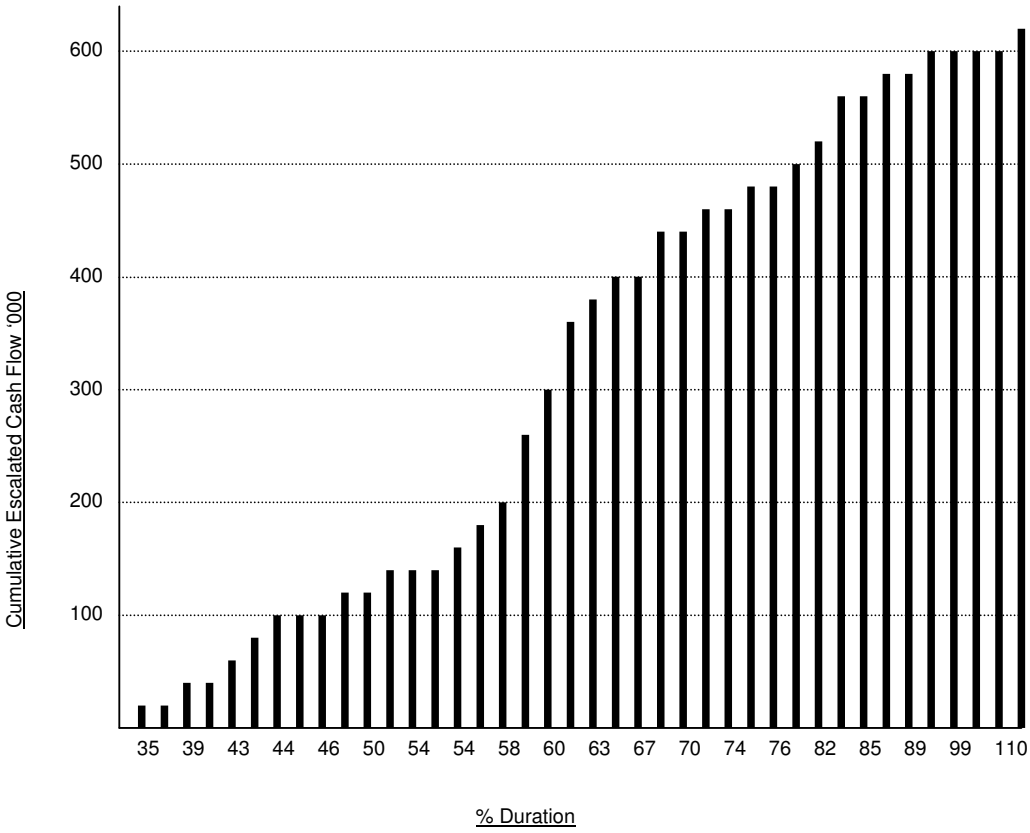

Figure 4.7: Cumulative escalated cash flow

Source: Louw, 2002: 100

2.2 Estimate range

The estimate range is intended to communicate the project team's level of confidence in the completeness of the current scope and the potential for variations in the ultimate scope (Noor *et al.,* 2006: OWN.05.1). The range and contingency are collective assessments of varying levels of risk (Shaheen, Fayek & AbouRizk, 2007: 325). Contingency and risk are reflected in the accuracy range and are very dependent and are not disconnected. Maddex (2008: RISK.03.1) states that contingency applications impact on the range of accuracy. Table 4.4 shows suggested contingency and ranges pertaining to the cost estimate. Also refer to Figure 3.32 in Chapter 3 of this study.

"Normal" contingency and range chart (applied against lowest reasonable bid/cost)						
Level of estimate	Mature technology		New technology		Retrofit project	
	Contingency	Accuracy range	Contingency	Accuracy range	Contingency	Accuracy range
OOM	25%	±50%	30%	±50% to 75%	25%	±50%
Conceptual	20%	±25% to 30%	25%	±40% to 50%	20%	35% to 40%
Accuracy range is based on a 50/50 chance of cost over/under run						

Table 4.4: Suggested contingency and ranges around the cost estimate
Source : Kinney and Soubiran, 2004: EST.15.12

A proper conceptual cost estimate starts with planning of the estimate, factoring costs and analysing and applying contingency. The most important aspect of conceptual cost estimating is the use of proper factors. These factors are most reliable when derived from historical cost data and the estimator should differentiate between ISBL and OSBL areas. This is necessary because OSBL scope normally consists of typical brown field construction work which makes the use of factored quantities and costs very dangerous. When the estimate has been completed and the contingency allocated, the estimator should also make an allowance for escalation on the project. All of this added together will provide the project team with some sort of confidence level which will be expressed as an estimate range.

3.0 TYPES OF CONCEPTUAL ESTIMATING

The preceding discussion on conceptual estimating outlined the basis of this form of estimating in general. Following these steps one should be able to perform a conceptual estimate of average accuracy. To improve the accuracy range of this estimate the different types of conceptual estimating should be discussed to understand the pitfalls and advantages of each technique (Shekaran, 2008: 12).

This estimate form has been briefly discussed in Chapter 3 of this study. The main difference between this form of estimating and detailed or deterministic estimating is that conceptual estimating normally takes place at the beginning of a project (Ashworth, 1996: 6). As construction drawings and specifications generally are not available during the early stages of a construction project, conceptual estimating normally takes place without the take-off of quantities. Ballentine and Gignac (2008: TCM.04.2) state that the level of accuracy of the conceptual cost estimate mainly depends on the level of information available and the techniques being used to determine the conceptual cost estimate. The accuracy of an estimate at a certain information level could be improved by using the proper technique for the available data.

Several modeling techniques have been suggested for conceptual estimating including probabilistic modeling, regression analysis, neural networks, ratio estimating and parametric estimating (Cummins & Jenks, 1989: 15). This study focuses more on ratio conceptual techniques, but an understanding of the other methods is also necessary to grasp the full extent of this form of plant estimating.

3.1 Probabilistic cost estimation

The most commonly used conceptual estimation techniques stem from the probabilistic cost determination of process plants. It is therefore the quickest way for quantifying uncertainties included in the early cost estimate. These techniques require historical cost data of previous construction projects (Hassanein, 2006: PS.17.02). A probability distribution function is selected for the cost data by fitting the data against major theoretical distribution functions and comparing goodness of fits. Beta and log-normal distributions are normally used, however selecting the distribution function for a specific data set may depend on the characteristics of the project data and other distribution functions may provide better fits (Sorenson & Lavelle, 2008: 44; Singh, 2007: 29).

Probabilistic cost estimation for construction projects may be performed at different levels. As an example for building projects Level 0 may include total cost and Level 1 may include system level of cost breakdown such as structure, electrical, mechanical, etc. If probabilistic cost estimation is done at Level 0, the only data required will be historical data of total cost of past projects. The cost of each project could then be adjusted for inflation (escalation) and location with the use of historical and location cost indices (Touran, 2003: 281). A unit cost ($/m2) could then be calculated with the

adjusted cost data set and this data set could be used for selection of the probability distribution function. Once the distribution function is selected cost estimates for different probabilities can be computed and range estimating can be performed (Vargas, 2004: CSC.16.03).

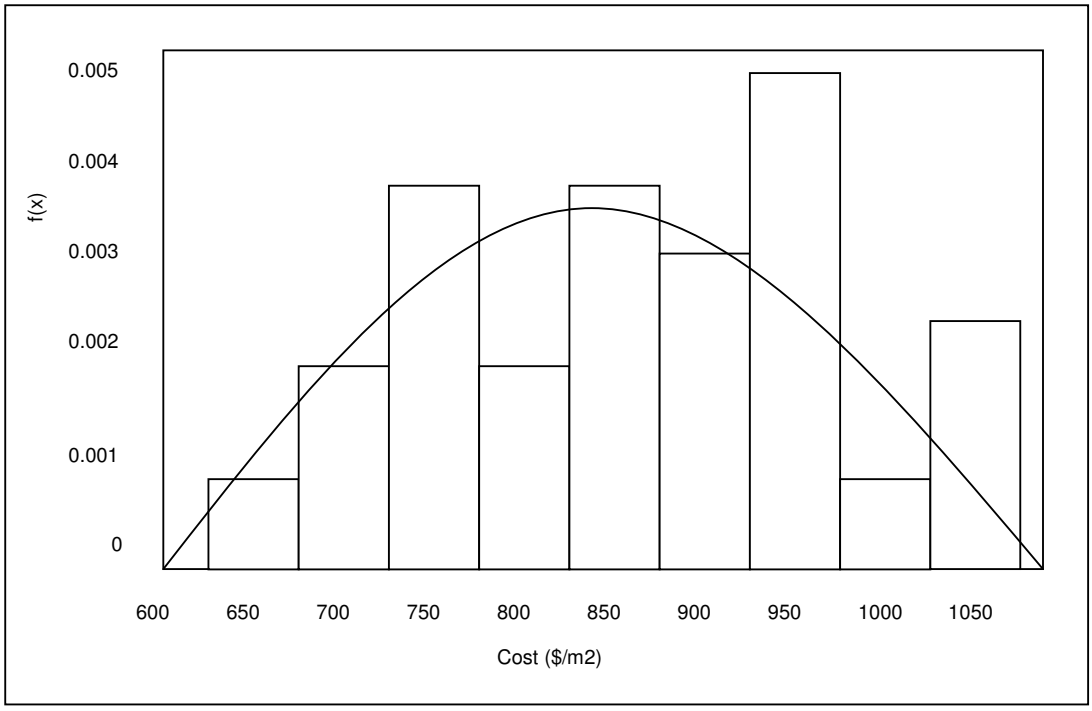

Figure 4.8: Plot of project cost data and fitted probability distribution
Source: Sonmez, 2005: EST.07.2

Sonmez (2005: EST.07.1) illustrates the working of probabilistic estimating by means of an example. He refers to data of 30 building projects which were constructed in 14 states over a 20 year period that were used to develop range estimates at Level 0 with the probabilistic cost estimating technique. Figure 4.8 demonstrates the functioning of range estimating which is the invert function of the graph as demonstrated in Figure 4.9.

A 10% to 90% range estimate for the unit cost ($/m2) has been developed with the distribution function selected. Figure 4.9 demonstrates this range. The range estimate indicates that there will be an 80% chance that the actual cost will be within the range of 687.5 – 940.2 $/m2, and that there is a 10% chance that the actual cost will be lower than 687.5 $/m2 and higher than 940.2 $/m2. The range estimate gives an idea of the degree of uncertainties included in the estimate.

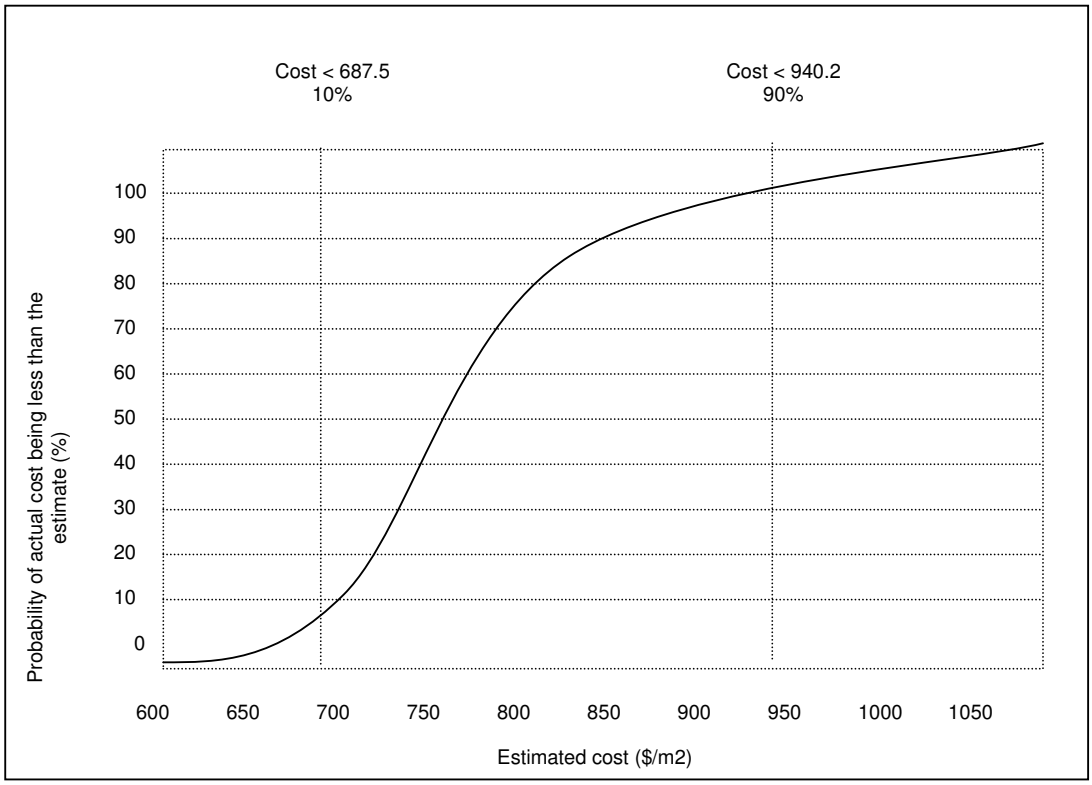

Figure 4.9: Range estimation with probabilistic modeling

Source: Sonmez, 2005: EST.07.2

Probabilistic cost estimation at Level 1 requires detailed statistical analysis. First cost data has to be compiled and adjusted for inflation and location at Level 1 and a probability distribution function cost of each system such as structure, electrical, mechanical, etc. has to be selected. Depending on the characteristics of the cost data for each system, different probability functions may provide better fit to the data sets. Correlations among cost of each system need to be calculated after selection of the probability distribution functions. Considering correlations amongst systems is very important for accurate estimation of costs and variations of the cost estimate. Finally cost estimating can be performed by use of a Monte Carlo simulation technique (Hollmann, 2007a: RISK.03.1).

The bottom line of a model may be a function of hundreds or thousands of uncertain variables. A random number based technique, the Monte Carlo Method, may be applicable and useful (Vrijland, 2005: DEV.06.1). With modern computers, the computing power is available to perform millions of calculations within seconds, which makes the use of Monte Carlo simulations practical. Whiteside (2008: EST.04.1)

indicates that in the multi-variable case, a mathematical model is developed containing all relevant variables, preferably restricted to those with a significant impact on the bottom line. Verschoor (2005: RISK.10.1) points out that the model gets calculated many times, in every trial assigning a fresh random number based value to each of all the input variables. The assigned value will be within the probability range of each variable (Vargas, 2004: CSC.16.1).

3.2 Ratio conceptual estimating

Page (1996: xvi) suggests two types of factored conceptual estimating in the petrochemical industry. The first method (when properly applied) can produce semi-definitive estimates with an accuracy range of ± 10%, while the second method relies on ratio estimating and is based on the known equipment material value and the application of weighted percentage costs for all other items. It produces an estimate with an accuracy range of ± 30% (Kwak & Watson, 2005: 1431).

Page (1996: xvii) describes the more accurate "Method One" as a process where major discipline quantities are determined, hence the reference of a "semi-definitive" estimate, and then cost accordingly. To achieve the desired level of accuracy the following information will be required:

- Plant capacity, product form, basic process and raw material.
- Total general specifications.
- Plant location (site conditions).
- Preliminary soil report with foundation recommendations.
- Plot plan and equipment arrangements.
- Mechanical flow sheets.
- Equipment lists.
- Building listings, type, size and description.

"Method Two" as described by Page (1996: xvii) can be referred to as Ratio Conceptual Estimating and is used in situations where the total cost of an item or facility can be reliably determined from the cost of a primary component. In the case of most petrochemical plants, the specialised process equipment makes up a significant portion of the total project cost. This is often referred to as "equipment factor" estimating (Uppal, 2007: EST.03).

According to Nitithamyong and Skibniewski (2006: 80), equipment factored estimates are used to develop costs for process and utility units for which the behaviour of the costs of the direct labour and bulk materials used to construct the facilities is correlated with the costs (or the design parameters) of the major equipment. Liu and Zhu (2007: 91) state that this estimating methodology typically relies on the principle that a ratio or factor exists between the cost of an equipment item and the costs for the associated non-equipment items (foundations, piping, electrical, etc.) needed to complete the installation.

An equipment factored estimate can typically be generated when project definition is approximately 1 to 15% complete. An equipment list should be available at this point of the estimate. This estimate is often a feasibility estimate used to determine whether there is sufficient business case to pursue the project. Shen and Liu (2003: 486) state that if there is sufficient business case to pursue the project, then this estimate may be used to justify the funding required to complete the engineering and design required to produce a funding or budget estimate (Newnan *et al.,* 2004: 46).

Louw (2002: 88) makes reference to the increased accuracy of the equipment factored method over that of the capacity factored method which is described later in this chapter. In Table 4.5 certain minimum equipment description requirements are depicted as applicable equipment factored estimating. Louw uses the example of the cost estimation of a pressure vessel where one would at least require the internal diameter, the tangent-to-tangent length, the internal pressure and temperature, and material of construction.

The estimator assumes that the general engineering specifications which applied to previous purchases will likewise apply to this equipment list, and searches the accumulated price and technical data for comparably rated pieces of equipment. Xiao and Proverbs (2003: 325) state that the estimator can also obtain commercially binding quotations for the equipment. As soon as the equipment list is priced, the cost of other elements in the plant is estimated by assuming a certain pattern will apply.

Boilers	Capacity t/h or MW duty, pressure, superheat temperature, type
Furnaces	Duty in MW, materials of manufacture, fuel feed rate, type
Flares and stacks	Height, diameter, materials of manufacture, flare tip specifications, capacity t/h

Heat exchangers	Total heat exchange surface area, finned area for air cooled heat exchangers, materials of manufacture, type, e.g. shell-and-tube, floating head, fixed tube, double pipe, U-tube, plate, air cooled, MW duty for plate exchangers
Reactors	Tangent-to-tangent length, inside diameter, pressure, temperature, materials of manufacture, type, e.g. fixed bed, fluidised bed, vapour phase, slurry
Distillation columns	Tangent-to-tangent length, inside diameter, pressure temperature, materials of manufacture, type and number of internals, e.g. valve trays, structural packaging, bubble cap trays
Tanks	Diameter, height, pressure, materials of manufacture, type, e.g. fixed roof, floating roof, sphere, bullet
Drums and separators	Tangent-to-tanget length, inside diameter, pressure, temperature, materials of manufacture, type, e.g. horizontal, vertical, with or without boots, semi-elliptical heads, hemispherical heads, internals, e.g. heating coils
Filters	Capacity m^3/h, pressure, temperature, materials of manufacture, type, if possible filter area and particle retention size
Compressors	Capacity m^3/h at suction conditions, kW rating, inlet and discharge pressures, medium compressed, type, e.g. reciprocating, centrifugal, axial, driver type, e.g. steam turbine or electric motor, if possible temperatures and number of stages
Pumps	Capacity m^3/h, kW, type, e.g. centrifugal, driver type, inlet and outlet pressure, medium pumped, if possible net positive suction head
Dryers	Capacity t/h, kW, materials of manufacture
Centrifuges	Capacity t/h, kW, materials of manufacture
Crushers	Capacity t/h, kW, materials of manufacture, type, e.g. jaw, roller
Crystallisers	Capacity t/h, kW, materials of manufacture
Ejectors	Capacity t/h, medium pumped, suction and discharge pressure, number of stages, pumping medium and pressure
Mills	Capacity t/h, kW, type, medium milled, speed
Mixers	Power kW, speed, materials of manufacture, type
Refrigeration units	Duty MW, coolant type, evaporator temperature, type
Cooling towers	Duty MW, capacity, e.g. water flow m^3/h, materials of manufacture, type, e.g. induced draught, if possible cooling

	range, wet bulb temperature
Boiler water treatment system	Capacity t/h, quality of feed and of product e.g. total dissolved solids in parts per million, materials of manufacture, type, e.g. ion exchange or reverse osmosis
Conveyors	Capacity t/h, kW, length, width, material to be handled, type, e.g. rubber belt, bucket
Cranes	Lifting capacity, tons at given radius (m), type, e.g. overhead, tower
Lifts and elevators	Capacity (t), duty, e.g. freight or personnel, speed m/s, type
Hoists	Load (t), speed m/s, type

Table 4.5: Equipment design details: minimum requirements
Source: Louw, 2002: 53-54

Table 4.6 offers an example of the total cost of a process plant Type X, having a Capacity of Y tons per annum, expressed as proportions of the mechanical equipment cost. This gives an idea of how much needs to be added in addition to the mechanical equipment to make it a functioning whole (Yan Xiaoyan, 2004: 3).

Plant type X, capacity Y tons per annum	**Cost**
Mechanical equipment	100
Other materials	95
Labour for construction	55
Sub-total (direct field cost)	250
Other costs	150
Total cost	400

Table 4.6: Example of cost components as percent of mechanical equipment cost
Source: Louw, 2002: 89

In the *Conceptual Cost Estimating Manual,* Page (1996: 1-10) provides a list of the disciplines of work that should be taken into account when performing a Ratio Conceptual Estimate. The disciplines are illustrated in Table 4.7.

DISCIPLINES OF WORK	
	DIRECT COST ITEMS
Process equipment	The equipment cost, labour, material and sub-contracts necessary to set and erect or install the process equipment in the final position and condition for mechanical operation.
Site preparation	All general preparation of the plant site for construction including, but not necessarily limited to, clearing, rough grading, cut, fill, borrow, disposal, soil stabilisation and finish grading.
Site improvements	Includes items of work that provide permanent improvements to the plant site, such as drainage ditches, culverts, storm drain pipes, canals, dikes, all base materials for roads, parking lots, and railroads including ballast, railroads, and fencing. Pavements for roads, process areas and parking areas are included under “Paving”.
Concrete	All earthworks, forms, reinforcing steel, miscellaneous embedded items and placing, finishing and curing of concrete for equipment foundations and equipment structures are included. All building concrete including foundations is included under “Buildings”.
Structural steel	All cost for procuring, fabricating, and erecting structural and miscellaneous steel, not embedded, for framed structures, equipment supports, equipment platforms, walkways, ladders, handrails and pipe supports. Steel for buildings is

DISCIPLINES OF WORK	
	included under “Buildings”.
Buildings	All cost of buildings including earthworks, foundations and other concrete, total superstructure, HVAC, plumbing and utility piping to outside of building, insulation, small power and lighting, painting and all architectural finishes.
Underground piping	All project underground piping serving the project including fire water loops and their components, water lines and special process lines.
Above ground piping	Fabrication and erection of all above ground process piping, valves and fittings required for plant operation. Installation only of relief valves, control valves, and orifice fittings for instrumentation are also included. The material cost for these instruments are, however, included under “Instrumentation”.
Underground electrical	All labour and material for underground power and lighting, ducts, conduit, wire, cable, etc. Also includes earthwork and concrete for embedments.
Above ground electrical	All items required for the complete above ground power and lighting systems for the total project, excluding buildings. Also includes the installation of all electrical instruments and their hook-ups.
Instrumentation	Includes material and labour for instrumentation work defined as follows: - material cost includes instruments, control valves, relief valves, control panels, meter runs, orifice fittings and all other instrument items plus tubing, tube bundles, and tray materials required to install

DISCIPLINES OF WORK	
	such items; - labour cost includes the installation of the above except as noted; - labour cost to install relief and control valves and orifice fittings is included under “Above Ground Piping”. Labour cost to install electrical hook-up is included under “Above Ground Electrical”; - all header piping labour and material costs are included under “Above Ground Piping.”
Insulation	All labour and material cost of insulation, refractories, and linings for process equipment and piping. Building insulation is included with “Buildings”.
Painting	Includes all preparation and protective coating of surfaces with paint and/or epoxy for the total project excluding buildings.
Paving	Includes the furnishing and placing of concrete, asphalt, or gravel used for the final surfacing of roads, sidewalks, parking areas and process work areas as required.
Proratables	Includes the labour and material cost for the daily area clean up, all required scaffolding and final test, startup, and pre-commissioning assistance.
	<u>CONSTRUCTION EQUIPMENT</u>
Rental or purchase	Cost of rental or purchase of construction equipment required for the project. Does not include small tools.
Service labour	All labour required to service and maintain the construction equipment. Does not include the operation of the equipment

DISCIPLINES OF WORK	
	when working.
Fuel, oil, grease, supplies	Includes the cost of all fuels, lubricants, and supplies required to operate and maintain the construction equipment. OVERHEAD AND INDIRECT COSTS All or part of the items described below are used to establish costs for: - salaried indirect, - office hourly indirect, - field hourly indirect. The distribution will vary depending upon the type of project, local labour practices, and contractor preferences.
Engineering salaries – estimating	Civil, cost, electrical, general, mechanical and structural estimating salaries.
Engineering salaries – field and technical support	Project chief engineer, assistant project chief engineer, chief field engineer, civil, electrical, mechanical, structural, field, staff, office, piping, instrument engineers, coordinators, engineering draftsmen, party chiefs, instrument men, chainmen, rodmen and labourers temporarily assigned to a field party performing general layout work.
Watchmen and janitors	Security supervisor, security coordinator, guards, watchmen, janitors. This does not include for contract security personnel.
Holiday pay	Pay for holidays not worked. Personnel covered by overhead and indirect estimate only.

DISCIPLINES OF WORK	
Salaries – office clerical	Administrative clerks, office clerks and secretaries
Quality assurance – labour	Chief construction inspector, construction inspectors, welding inspector, piping inspector, electrical inspector, boiler inspector and civil inspector.
Salaries – sub-contract administration	Salaries for sub-contractor coordinators.
Salaries – cost engineering	Salaries for cost/schedule supervisor, chief field cost engineer and cost engineers.
Salaries – scheduling and planning	Salaries for chief field scheduler and planner/schedulers.
Salaries – technical clerks	Salaries for clerical technical personnel.
Material control labour	Material control coordinators and material control personnel assigned to implement and follow-up the material control programme.
Move in/out labour	Job payroll labour for loading, unloading and transporting from facilities to project construction area tools and construction equipment, temporary facilities, etc. Move-in is defined as assembly of tools and construction equipment at jobsite. Move-out is the return of tools and construction equipment to other approved destination in the immediate area of the project.
Non-productive labour	Wages paid to hourly employees during a temporary period

DISCIPLINES OF WORK	
	when work is stopped. Also wages paid to craftsmen for voting in accordance with union or government regulations. Welding test labour and jury pay differential. Work stoppages due to inclement weather and show-up time are considered in productivity factors used elsewhere.
Safety and medical expense – labour	Safety supervisor, safety inspectors and medics.
Salaries – office	Chief accountant, accountants, bookkeepers, invoice auditors, expeditors, chief time keepers, personnel manager, personnel clerks, data controllers, data entry operators, and procurement officers.
Salaries – supervision	Project manager, general superintendent, assistant project manager, assistant superintendent, administrative manager, office manager, area coordinator and master mechanic.
Sick pay	Wages paid overhead and indirect employees only for authorised absence due to personal illness, as approved by project construction manager.
Warehouse salaries	Warehouse supervisor, assistant warehouse supervisor, warehousemen, tool room attendants, warehouse labourers – assigned full time to warehouse operation. Must be on project payroll only.
	TEMPORARY CONSTRUCTION FACILITIES (Labour and material)
Temporary buildings and facilities – labour	Labour only for construction or erection, maintenance and dismantling of the temporary facilities, in accordance with but not limited to the following: roads, ditches, bridges,

DISCIPLINES OF WORK	
	storage areas, parking lots, fencing, buildings, water system, sanitary system, power distribution, telephone and communication systems, and plant and air system. Does not include construction camp, quartering or catering facilities.
Temporary buildings and utilities – material and supplies	Material and supplies and maintenance for construction and dismantling of the temporary facilities in accordance with but not limited to the following: rental of temporary field offices and warehouses, roads, ditches, bridges, storage areas, parking lots, fencing, buildings, water system, sanitary system, power distribution, telephone and communications system. Does not include construction camp, quartering or catering facilities.
	LABOUR BURDENS AND OVERHEAD PERSONNEL BENEFITS
Retirement and savings plan (for overhead and indirect personnel only)	Actual cost fixed by appropriate accounting office. Does not include any like or similar item which is a part of a union fringe benefit.
Insurance – employees' life and hospitalisation (for overhead and indirect personnel only)	Direct premium charges only. Does not include any like or similar item which is a part of a union fringe benefit.
Taxes – payroll	Unemployment contributions, etc.
Vacation pay (for overhead and indirect personnel only)	Actual cost for overhead and indirect personnel only based on gross payroll as billed by the appropriate Accounting Office. Does not include any like or similar item which is a

DISCIPLINES OF WORK	
	part of a union fringe benefit. SMALL TOOLS AND CONSUMABLES
Construction supplies	This account should include items that are consumed and are, by their use, directly related to construction, for example, sandpaper, rope, chalk, soapstone, emery paper grinding wheels, moil points, saw blades, padlocks, threading dies, drill bitts and reamers, rags, brooms and mops, air and water hose for general use.
Small tools (in accordance with contract limits)	Purchase or rental of hand tools, power operated hand tools, etc. Rental or repair parts for such tools will be included in this account. This account includes minor equipment such as small pumps up to 3", vibrators, light plants (up to 3,000 watt), chain saws, pipe threaders, tar pots, small sand blasting machines, air and chain hoists.
Workmen's supplies	This cost will include items that are, by their use, directly beneficial to and for the convenience of the workmen, for example, towels, toilet paper, drinking cups, ice drinking water, hard hats, protective clothing, gloves, boots, salt tablets, soap and safety shoes. Credit is to be received for sales by payroll deduction for items charged here. OTHER INDIRECTS
Advertising	Classified ads, public advertisements.
Bond premiums	Bid bonds, performance bonds, maintenance bonds, and fidelity bonds.
Communications and	Telephone, telegraph, teletype, postage, radio rental or

DISCIPLINES OF WORK	
postage	communication system rented from a third party. Includes data lines and couplers.
Containers	Deposits for returnable containers and reels.
Dues	Membership dues for clubs and professional organisations, for overhead and indirect personnel only. Does not include union dues.
Engineering supplies	Surveying instruments (purchase or rental), drafting supplies, surveying supplies, blueprint or photostat work, progress photos.
Expediting	Cost for services from expeditors who are not on the job payroll.
Heat, light, water and power	Public utility charges and heating fuels for job buildings. Cost for water not used for construction purposes.
Insurance – general	Premiums for builder's risk, fire and extended coverage, equipment, floater coverage, non-owned automotive liability, independent contractor's liability, contractual liability, special risk coverage, such as war risk heavy lift, hull and umbrella.
Legal	Abstracts, lawyers fees, court costs, notary fees, sign-up expense.
Licenses and permits	Business permits, construction permits, export/import licenses, government inspection fees, hauling permits.
Move in/out – supplies and services	Transportation of tools and construction equipment by others to project construction area and miscellaneous supplies consumed and services used for move-in and -out purposes.

DISCIPLINES OF WORK	
Office supplies	Stationary supplies, printing, office equipment purchase, rental or repair, office and warehouse forms and supplies, jobsite reproduction costs and furniture.
Safety and medical expense – material	Medical examination fees, medical supplies, safety signs and literature, first-aid equipment, fire extinguishers and refills.
Testing and laboratory analysis	Soil surveys, concrete cylinder tests, independent inspectors. Lab charges to test welders.
Travelling	Transportation and subsistence expense of overhead and indirect employees on business trips (excluding quality assurance personnel travel).
Welding supplies	All material, supplies and tools required by a welder, i.e. acetylene, oxygen, flux, welding rods, lighters, flints, chipping hammers, wire brushes, stingers, helmets, lenses, asbestos gloves, goggles, gauges, welding qualification test material, etc.
Unclassified	Flowers, weather reports and forecasts, and bank service charges.
Data processing services	Cost for data processing services for the project. Terminal rental, supplies, computer charges from outside jobsite sources, etc.
Consulting fees	Cost for outside consulting services which might be required in connection with the project which are not a part of engineering.

DISCIPLINES OF WORK	
Trade journals, books, publications and subscriptions.	Cost of books and subscriptions.
Contract guard service	Cost of subcontract guard service.
Quality assurance – material and supplies	Normally includes travel costs for quality control personnel.
Employee educational assistance	Cost of employee educational assistance for overhead and indirect personnel only.
	HOME OFFICE COST
Engineering/design services	Total labour and material cost for the complete engineering and design of the project including engineering fee.
Construction services	Services furnished by various home office departments such as estimating, scheduling, expediting, etc. as may be required to assist the project. Services are charged to the project only for time actually spent on the project.
Project general management	Includes the portion of time that the contractor's management staff applies in regard to overall direction of the project.

Table 4.7: Disciplines of work covered in ratio conceptual estimating
Source: Page, 1996: 1-10

As stated later in this chapter when discussing capacity factored estimating, the cost pattern (or functions of mechanical equipment cost) for a certain plant would only be valid under the same typical circumstances (Bentley, 1987: 43). One would not expect the same pattern for a platformer unit as for an ethylene plant or for an oxygen plant, and neither would a pattern found in the USA necessarily hold true for a country like

Germany or South Africa. The reason for this is the differences in labour rates, productivity, specifications, equipment and material prices.

Bertisen and Davis (2008: 120) mention that capacity as well as equipment factored estimating can only be made if a complete unit is involved. For modifications or additions more detailed scope descriptions would be required. Table 4.8 shows the make-up of a selection of different types of plant. It is interesting to note how wide the bottom-line figures vary, mechanical equipment to bottom-line cost ranging from a ratio of 1:6,92 to 1:1,68 (Louw, 2002: 90).

Brent and Labuschagne (2007:416) point out that an ethylene plant proportionally has much more piping than other types of refinery units, and this characteristic is highlighted by the item “other materials” as well as by the high labour figure.

Plant components as percent of mechanical equipment	Ethylene plant	Refinery Unit	Low temperature gas handling unit	Steam plant	Oxygen plant
Mechanical equipment	100	100	100	100	100
Other materials	109	82	82	52	28
Labour	190	128	46	40	20
Indirect field cost	135	147	77	15	9
Engineering, supervision, project management, etc	159	101	58	45	12
Total cost	**692**	**558**	**362**	**252**	**168**
Variance ratio	1:6,92				1:1,68

Table 4.8: Plant components as a percent of mechanical equipment

Source: Louw, 2002: 90

The equipment and other materials of the "low temperature gas handling unit" given here is more expensive than normal carbon steel, hence the labour and other items are comparatively smaller. An oxygen plant has very expensive equipment such as air and oxygen compressors and other equipment fabricated in aluminum or stainless steel, hence the very high proportion in equipment (Louw, 2002: 90).

Table 4.9 shows an example of equipment factored cost estimating, based on the carefully recorded cost history of a previously built carbon steel refinery unit constructed some time ago. The table gives all the cost items as percentages of the total estimated cost of all mechanical equipment. Kapp (2004) points out that escalation is dependent on the particular time schedule of the project. Contingencies depend on the risk of the particular project (Prasad, 2008: EST.S02.3). The mechanical equipment was estimated piece by piece based on an equipment list with sizes, materials and ratings, as given by the process designer, and using in this case historical prices being updated to the present date by applying the appropriate escalation indices (Morris & Wilson, 2006: CSC.06.2).

Carbon steel refinery unit	**% of ME**	**% of ME**	**% of ME**	**Estimated cost of proposed plant**
Estimated mechanical equipment cost (ME)	100	Materials	Labour	1,000,000
Site preparation and earthworks	5.1	2.0	3.1	51,000
Concrete	5.1	2.0	3.1	51,000
Structures	15.2	7.6	7.6	152,000
Buildings	2.5	1.0	1.5	25,000
Mechanical equipment	100.0	100.0	0	1,000,000
Mechanical equipment erection	6.2	0	6.2	62,000
Piping	52.4	31.4	21.0	524,000
Electrical	15.9	12.7	3.2	159,000
Control systems	26.3	19.7	6.6	263,100
Insulation and painting	8.3	4.6	3.7	83,100
Direct field cost	237	181.1	55.9	2,370,200
Indirect field cost	19.8			198,200

Carbon steel refinery unit	**% of ME**	**% of ME**	**% of ME**	**Estimated cost of proposed plant**
In-house engineering	7.5			74,700
Engineering & other services	98.0			980,100
License fees	19.0			189,600
Insurance	1.1			10,600
Catalysts & chemicals	0			0
Operations (capitalised)	12.6			126,400
Customs duties	6.5			65,300
Total without contingencies	401.5			4,015,100
Contingencies	20.0			802,384
Total before escalation	421.5			4,817,484
Spares	10.5			105,292
Operations (Operating cost)	4.0			40,000
Escalation	33.7			337,224
End-of-job cost (EOJC)	**469.7**			**5,300,000**

.

Table 4.9: Factoring by equipment cost

Source: Louw, 2002: 91

Another factored type estimate is described by Louw (2002: 86) and refers to Capacity Factored Conceptual Estimating. This method is not that common, but is sometimes used when output capacities are known (Ellsworth, 2007: 27).

For process plants, capacity factored estimates assume that the cost of the proposed plant will follow certain mathematical rules that have been found to be true in numerous previous cases (Louw, 2002: 86). In the case of plant capacity, the rule most frequently applied is illustrated as follows:

$$\frac{\text{Cost of Plant A}}{\text{Cost of Plant B}} = \left(\frac{\text{Capacity of Plant A}}{\text{Capacity of Plant B}} \right)^{n}$$

Note that the value of the exponent “n” in this relationship would only be true for a given technology, process and location which means a certain climate, topography, distance from sources of equipment and materials, the infrastructure available and the

availability of skilled craftsmen and experienced engineers or other professions (Jansen-Rommijn, 2008: EST.13.1). It would also only be valid for a certain range of scale-up or scale-down ratios. Despite these qualifying statements, the tool is useful for quick comparisons (Kelly, 2005: CDR.13.1).

3.3 Regression analysis

Conceptual cost estimates are not expected to be precise since project scope is not finalised and very limited design information is available during the pre-design stages of a project. A quick, inexpensive and reasonably accurate estimate is needed, based on the available information (Lowe, Emsley & Harding, 2006: 750). Regression analysis is one such method. Sonmez (2004: 677) states that in regression analysis the project cost is estimated with a regression model including a number of independent variables. He also mentions that some authors suggest using location, construction year, plant type, technology, etc. The use of regression analysis is not only limited to construction cost estimation. Zayed and Halpin (2005: 779), Edwards, Holt and Harris (2000: 45) and Blyth and Kaka (2006: 82) refer to several uses of regression analysis and how this concept can be extended to be functional in construction cost estimation.

Sonmez (2004: 677) states that in regression analysis the project cost is estimated with a regression model including a number of independent variables. Plant location, year of construction, plant type, etc. can be used as independent variables. The advantage of regression models lies in their generally economical use of parameters compared to some other techniques (Lowe *et al.,* 2006: 750). The technique of regression analysis, however, requires the user to make decisions about the use of interaction terms and also about the class of relationship (linear, quadratic, etc). Trost and Oberlender (2003: 198) point out that one of the main advantages of probabilistic estimating techniques is their capability to develop a range of estimates for quantifying the uncertainty of the estimate. In simulation, however, a probability distribution function needs to be selected to model the data (Sonmez, 2004: 678). The importance of regression analysis can also be found in parametric estimates which will be discussed later in the chapter.

3.4 Neural network analysis

A neural network is a form of artificial intelligence which could also be used for conceptual cost estimation. Bhokha and Ogunlana (1999: 133) and Ko and Cheng (2007: 317) point out that these networks have the capability to capture the relations

between independent and dependent variables. Kuprenas (2008: CSC.05.1) states that location, contract duration, size of the contract and type of project all have a measurable effect on construction cost. Edwards *et al.,* (2000: 46) point out that neural networks, similar to regression analysis, require the historical data of past projects so that it can capture the relations between variables and cost. Sonmez, (2004: 678) comments on the use of neural networks when performing conceptual estimates and how this form of analysis can assist the estimator.

Walsh, Sawhney and Vachris (2006: 125) indicate that to make estimates of construction cost sensitive to factors that influence their values, thereby freeing estimates of future costs from the assumption that past conditions will prevail in the future, procedures have been developed that use historical data to relate construction costs to the factors believed to influence them (Wilmot & Mei, 2005: 765). Typically, regression analysis has been used to establish this relationship but recent applications include the use of artificial neural network (ANN) and neuro-fuzzy models (Ezeldin & Sharara, 2006: 650). These relational models are different to the trend models since they only assume that the relation between construction cost and the influential factors will remain constant and not that past trends are unchanging (Fayek & Oduba, 2005: 940; Knight & Robinson, 2002: 505). Mazouk and Moselli (2004: 879), Moselli and Alkass (2006: 1196) and Omitaomu and Badiru (2007: 159) also comment on the use of fuzzy logic, which is a form of neural networking, in estimating construction related activity costs.

The linear relationship in linear regression imposes a functional relationship which may not always be appropriate (Chehayeb & Al-Hussein, 2006: CDR.18.1). While this may be at least partially addressed through transformation of variables, the assumption of a specific mathematical formulation limits the ability of the model to fit the data on which it is estimated (Skorupka, 2004: RISK.15.1). In contrast, neural network (NN) models have no implicit functional form and therefore have greater freedom to fit the data than regression models (Elazouni, Ali & Abdel-Razek, 2005: 33).

3.5 Parametric estimating

SCEA (2005: 3) reports that current industry and government practitioners commonly use parametrics to perform a variety of analyses, such as independent cost estimates and trade studies. Practitioners have argued that proposal preparation, evaluation and negotiation costs, and cycle time can be reduced considerably through the increased

use of parametric estimating (Dysert, 2008: EST.03.1 and Kapetanios & Marcellino, 2009: 210). They also state that these benefits can be achieved while maintaining or improving the quality of estimates produced.

Beginning in the early and mid 1990's, both the American industry and government, through the Parametric Cost Estimating Initiative (PCEI), evaluated the ability of parametric estimating techniques and tools to support government proposal cost estimating requirements (Noor, Grumo, Kniskern & Kopach, 2006: OWN.05.2). The key issues considered included parametrics' ability to maximise the use of historical data in the estimating process, increase the estimate's realism, and reduce the cost associated with proposal preparation, evaluation and negotiation. SCEA (2005: 4) indicates that the PCEI, through numerous workshops and the Parametric Estimating Reinvention Laboratory, concluded that parametric techniques and tools, when properly implemented and correctly used, could produce realistic cost estimates at significantly reduced costs and times.

The benefits of using parametric estimating are well documented. It is estimated that savings to proposal preparation are between 40% and 80% when compared to some other approaches of estimating. Dysert (2008: EST.03.1) and Kwak and Watson (2005: 1430 – 1431) state that parametric tools and techniques have much more versatility than other estimating approaches. The following describe some reasons for this:

- Better estimates are provided, often in a matter of minutes.
- There exists a high-quality link between the technical and cost proposals.
- The data is well understood through the calibration and validation activities.
- It is much easier to estimate conceptual designs.
- Early costing cannot be done effectively any other way.
- No bill of material (BOM) is required.
- It is much easier to handle scope, technical and performance changes.

3.5.1 What is parametric estimation/analysis?

Dysert (2008: Est.03.1) describes parametric estimating as follows:

> *"A parametric estimate is comprised of cost estimating relationships and other parametric estimating functions that provide logical and*

> *repeatable relationships between independent variables (such as design parameters or physical characteristics) and the dependant variable (cost).”*

Kwak and Watson (2005: 1430 – 1431) demonstrate that the parametric estimating technique does play a significant role in the early stage of a project lifecycle regardless of the assertions that the results may lack the precision of the detailed estimate. Figure 4.10 demonstrates a suggested timeline for parametric estimating. Kwak and Watson (2005: 1430) propose a parametric estimate terminology to be as follows:

> *“A parametric estimation is obtained by using Cost Estimating Relationships (CER) among the project characteristics and applying an algorithm to determine an approximation of the total project cost. The characteristics may be physical attributes, performance specifications, or functions.”*

Polla (2007: 12) simplifies what seems to be the generalised conception of what parametric estimating involves and makes the following statement:

> *“Parametric estimating is a technique that uses simple to complex statistical relationships between historic data and applicable variables to calculate an estimated cost for a specific item or task.”*

Parametric analysis involves computerised cost models that use the parameters of consequential projects and the project’s products to estimate the use of resources required to perform the project such as labour, materials and time (Polla, 2007: 12). Stewart and Mastenbrook (1983: 40) and Vis (2005) state that these models have economic value because, when properly designed and used, they can improve the accuracy of project estimates, reduce the likelihood of serious overruns of budgets and schedules, reduce the costs of preparing project proposals, and enable project leaders to consider more options with regard to the best way to proceed (Bidarra & Bronsvoort, 2000: 215).

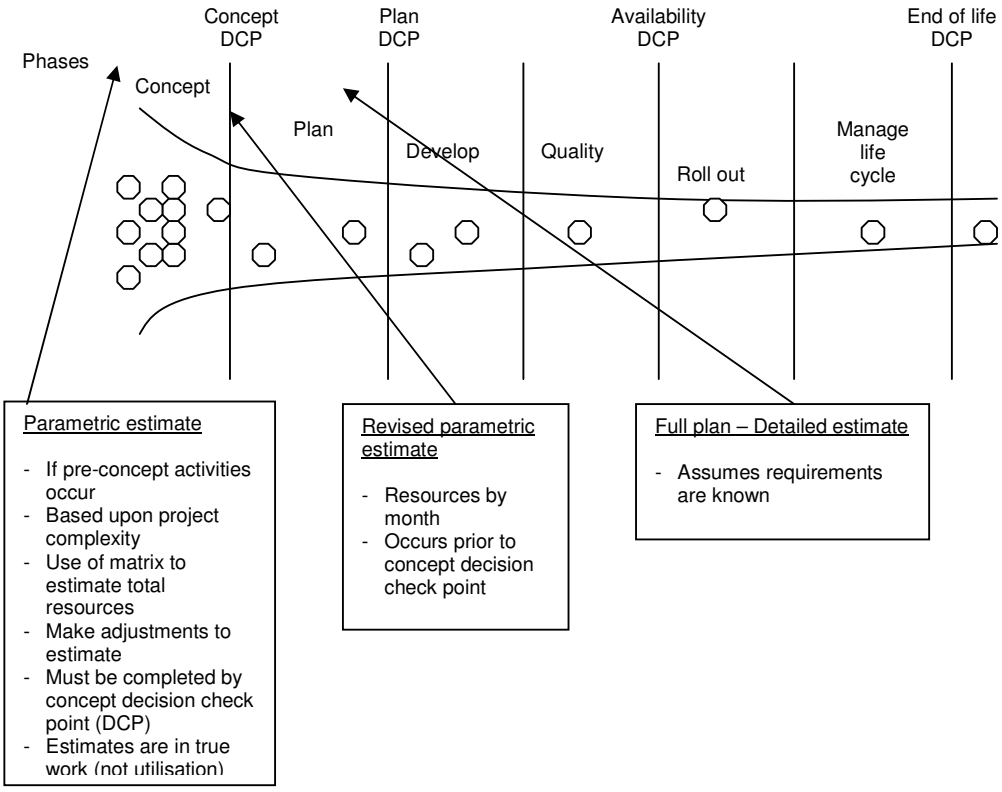

Figure 4.10: Suggested timeline for parametric estimating

Source: Kwak and Watson, 2005: 1431

Many parametric models also serve to advise on the uncertainties and risks associated with the project cost schedules (Iyer & Jha, 2006: 875; Khan, 2007: 14). This is an important function because modern projects are often complex. A purely cost or duration estimating model will provide what is called a “point estimate” of cost or duration. A point estimate is a single number that will always be in error to a greater or lesser extent (Polla, 2007: 15).

A model that deals with uncertainty and risk will provide a “range estimate”, also called a probability distribution, i.e. an estimate that tries to give some idea of the possible range of cost or schedule outcomes, and of the relative likelihood or particular outcomes (Sonmez, 2005: EST.07.1). The process of developing range estimates are inherently of more value to project management than point estimates because they help with understanding of what could happen and why (Smith, O’Keefe, Georgiou & Love, 2004: 264). They frequently point to certain risk abatement possibilities and

options that otherwise would have gone unnoticed (Maddex, 2008: RISK.03.1; Noor *et al.,* 2006: OWN.05.2).

The process of parametric estimating has three main components: database development, model development and model use (Camargo, Rabenasolo, Jolly-Desodt & Castelain, 2003: 2). Parametric analysis is a major management innovation. In common with several other management innovations, such as network scheduling and earned value analysis, modern parametric analysis has its genesis in the US and British military-industrial complex. The use of parametric analysis also has seen increased employment in the construction industry in recent years. Prentice (2004: 2), Ruskin (2004: 27) and Buell (2008: EVM.07.2) all comment on the use of earned value analysis and how that slots in with construction cost estimation and in particular, parametric estimating.

The first step in developing a parametric model is to establish its scope (Dysert, 2008: EST.03.2). This defines the end use of the model, the physical characteristics of the model, the cost basis of the model, and the critical components and cost drivers. The end use of the model is typical to prepare conceptual cost estimates for a process plant or system (Kapetanios & Marcellino, 2009: 209). The model should be based on actual costs from completed projects, and reflect the organisation's engineering practices and technology (Cass, 2007: 18). The model should generate current year prices or should be able to escalate to current year costs. The model should be based on key design parameters (Fang & Rogerson, 1999:45) that can be defined with reasonable accuracy early in the project scope development, and should provide the capability to be easily adjusted for specific complexity or other factors influencing the costs. Figure 4.11 shows a diagram of the typical steps that will have to be followed to build a parametric model.

3.5.2 The parametric model building process

The development and normalisation of historical auditable historical data is a key starting point in parametric model development (Pickett & Elliott, 2007: EST.02.2). The historical data will dictate and restrict the level of detail and the approach the parametrician can take (Kaka, 1999: 260; Melamed *et al.,* 2007: RISK.06.2).

3.5.2.1 Database development

Musgrove (2008: EST. 07.1) points out that a sound database of historical information is important to a successful parametric estimate. A cost model is a forecast of future costs based on historical fact (Park, Han & Russell, 2005: 164). Thus, future cost estimates must be consistent with historical data collection and cannot provide a lower level of detail than provided by the historical detail without some allocation or distribution scheme devised by the parametrician. Dysert (2008: EST.03.2) points out that proper data collection is the basis of good parametric estimating and that the developed model can only be as good as the data it is based upon.

Parametric techniques require the collection of historical cost data and the associated non-cost information and factors that describe and strongly influence those costs (Stewart & Mastenbrook, 1983: 37). Data should be collected and maintained in a manner that provides a complete audit trail with expenditure dates so that costs can be adjusted for inflation (Kaka, 1999: 256; Melamed *et al.,* 2007: RISK.06.1).

Technical non-cost data describes the physical, performance and engineering characteristics of a system or individual item. For example, weight is a common non-cost variable used in cost estimating relationships (CER's) and parametric estimating models (Camargo *et al.,* 2003: 3). A fundamental requirement for the inclusion of a technical non-cost variable in a CER is that it must be a significant predictor of cost.

Once collected, cost data must be adjusted to account for the effect of certain non-cost factors such as production rate, improvement curve and inflation – this is data normalisation (Oladapo *et al.,* 2008: 119). In Chapter 5 more can be found on the development of a database for estimating purposes.

3.5.2.2 Model requirements and architecture

The expectation of a parametric model is that it will estimate costs virtually instantaneously and accurately if the correct information is entered with respect to its parameters (Kwak & Watson, 2005: 1430). Each parametric model contains at least one cost estimating relationship (Ibrahim, Shash, Assaf & Jannadi, 2007: 18). Love, Tse and Edwards (2005: 187) and Lowe, Emsley and Harding (2006: 11) also comment on estimating relationships. These relationships are also known as CER's.

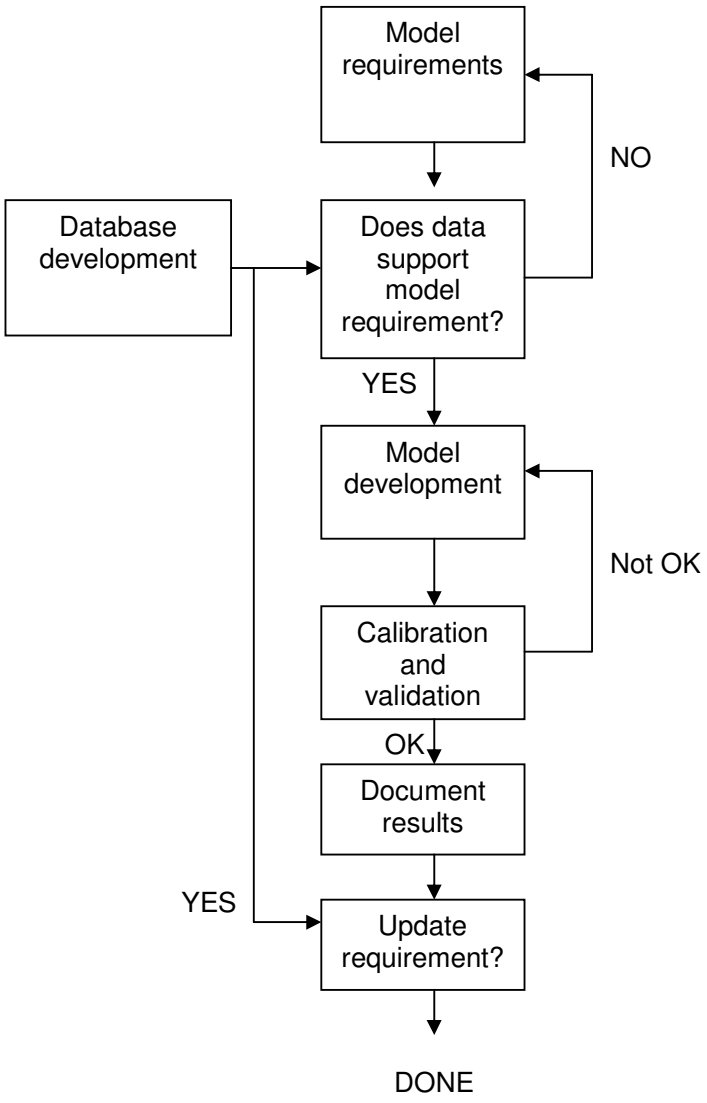

Figure 4.11: Flow chart of cost model development by the practitioner

Source: SCEA, 2005: 3

A CER is a mathematical relation and involves numbers, but otherwise can take several forms (Younossi, Areana, Moore, Lorell, Mason & Graser, 2002: 79). Two of the most common forms are algebraic equations and lookup tables. The most general expression for the algebraic equation is:

$y = f(x_i)$

Where:

y : a desired estimate (usually in currency, labour hours expended or periods of time consumed). Mathematicians will refer to “y” as a dependant variable.

f : represents some functional relationship that could be almost anything, including linear equations and a variety of non-linear equations such as polynomials, power laws, exponentials, and so forth. The key point about the selection of “f” is that the resulting equation must be a good fit to the supporting data.

x_i : represents the possibility of more than one independent variable. Most commonly, those independent variables are the parameters that the model builder has chosen as parameters driving the dependant variable. Model users initiate estimating by entering known or at least suspected values for these parameters.

A key aspect of model architecture is the choice of parameters. Younossi *et al.,* (2002: 79) point out that a prime requirement for use of a particular parameter is that it must be either a direct cause of the level or amount of the resource being estimated, or must strongly correlate with it. An example of a direct cause is the number of optical elements in a telescope. The more of them required, the higher the cost. Their optical quality is another direct cause, as is the combined surface area.

A requirement for the selected cost driving parameters considered as a set is that the amount of correlation between any two of them should be small (Vis, 2005: 1). Correlation is a statistical term. Nassar, Nassar and Hegab (2005: 1177) point out that the most used measure of it is the coefficient of variation (R^2). The coefficient measures the strength and the direction of a linear relationship between two variables.

Kapetanios and Marcellino (2009: 215) state that a commonly used parameter in estimating many types of hardware is its weight. In many cases, weight does correlate strongly with cost, but is seldom a direct cause. Attempts to reduce weight can increase cost significantly. Weight, however, is used because data for weight is almost always available. Reasonably accurate weights are normally available fairly early in the project, but when weight is used as a parameter, it will be necessary to use other parameters as well to prevent anomalous results as incorrect decreases in cost can occur when engineers attempt weight reduction programmes (Cocodia, 2008: 249).

When plotting data points on a graph, one can observe data scatter (Younossi *et al.,* 2002: 80). The most prominent reasons why data scatter occur are as follows:

- Poor choice of cost driving parameter – A parameter that is poorly associated with one project cost may be an excellent driver for a different project cost. For example, a driver that poorly predicts development labour hours could possible be a very good predictor of production labour hours.
- Presence of one or more other cost driving parameters – Most costs depend to some extent on more than one parameter.
- Presence of non-normalised parameter values – Inflation is one example of an effect that the economy can have on data from different time zones.
- Data collection errors – Data errors can occur when data is first recorded or when the analyst acquires it from wherever it has been stored.
- Inconsistent cost classification – Especially when data is sourced from different organisations with different accounting systems, data can be found to be inconsistent.
- Non-linearity of the x-y relationship.

3.5.2.2.1 Model calibration and validation

As mentioned, complex models are based on an organisation's historical data making them self-calibrating. The validation process, however, applies to all parametric estimating techniques. Validation is the process or act of demonstrating the complex model's ability to function as a credible estimating tool (Camargo *et al.,* 2003: 10). Validation ensures:

- The model is a good predictor of costs.
- Estimating system policies and procedures are established and enforced.
- Key personnel have proper experience and are adequately trained.

3.5.3 Cost estimating relationships (CER's)

A cost estimating relationship (CER) is the foundation of the art and science of estimating resources needed in projects using parametric estimating (Camargo *et al.,* 2003: 7). The parametric estimate comprises a collection of historical data, and reducing it to mathematical forms that can be used to estimate similar activities in future projects. These mathematical forms are called CER's. They are normally algebraic equations, but sometimes also tabulated data (Kwak & Watson, 2005: 1432). A CER is a mathematical expression which describes how the values of, or changes in,

a “dependent” variable are partially determined or “driven” by the values of, or changes in, one or more independent variables and describes how it behaves (Pratt *et al.,* 2005: 1252). Since a parametric estimating method relies on the value of one or more input variables, or parameters, to estimate the value of another variable, a CER is actually the quintessential parametric estimating technique (Camargo *et al.,* 2003: 6). In Figure 4.12 it is demonstrated how the number of cost drivers will influence the error margin of the parametric estimate.

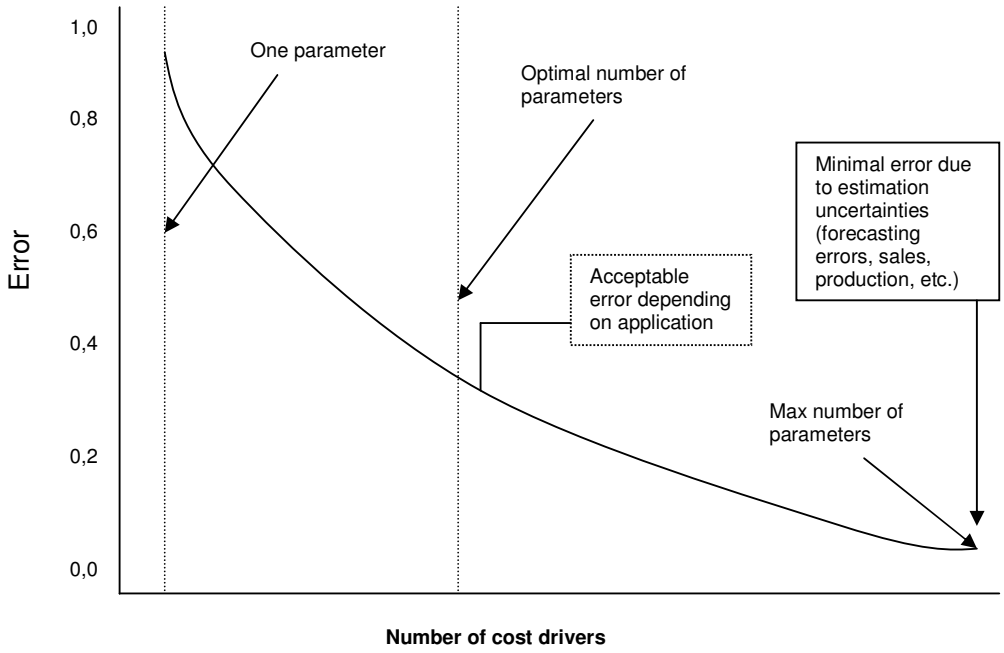

Figure 4.12: CER’s accuracy versus the number of cost drivers in the model

Source: Camargo *et al.,* 2003: 6

The dependent variable of a CER is cost or a closely related resource measure such as man hours. Younossi *et al.,* (2002: 75) state that the independent variable or variables are typically technical parameters that have been demonstrated to correlate with cost. In a cost-to-cost relationship, the independent variables are also cost, in other words, the cost of one element is used to estimate the cost of another. In a non cost-to-cost relationship, the CER uses a characteristic of an item to predict its cost. An example is where a CER estimates an item’s manufacturing cost based on its weight (Kapetanios & Marcellino, 2009: 208).

A CER is a valuable estimating tool and can be used at any time in the estimating process (SCEA, 2005: 3.2). For example, a CER may be used in the programme concept or validation phase to estimate costs when there is insufficient system

definition for more detailed approaches. CER's can also be used in a later phase in the programme as primary estimate or cross checks of non-parametric estimates. Camargo *et al.,* (2003: 6) indicate that parametric cost models comprised of several CER's can provide estimates at lower levels of definition. Before developing complex parametric models, analysts typically create simple CER's which demonstrate the utility and validity of the basic parametric modeling approach. Assiskumar (2008: EST.16.3) points out that the proper development and application of CER's depends on the collection and preparation of data on historical programmes and on applying appropriate mathematical and statistical techniques. Figure 4.13 is a schematic presentation of the CER development process.

3.5.3.1 Cost estimating relationship (CER) development

The structural foundation of modern cost analysis is the cost estimating relationship, statistically derived from historical cost data (Kaka, 1999: 260). CER's are usually expressed in the form of linear or curvilinear statistical regression equations that predict cost (the dependent variable) as a function of one or more cost drivers (independent variables). However, the CER only provides half of the information required to perform the estimate.

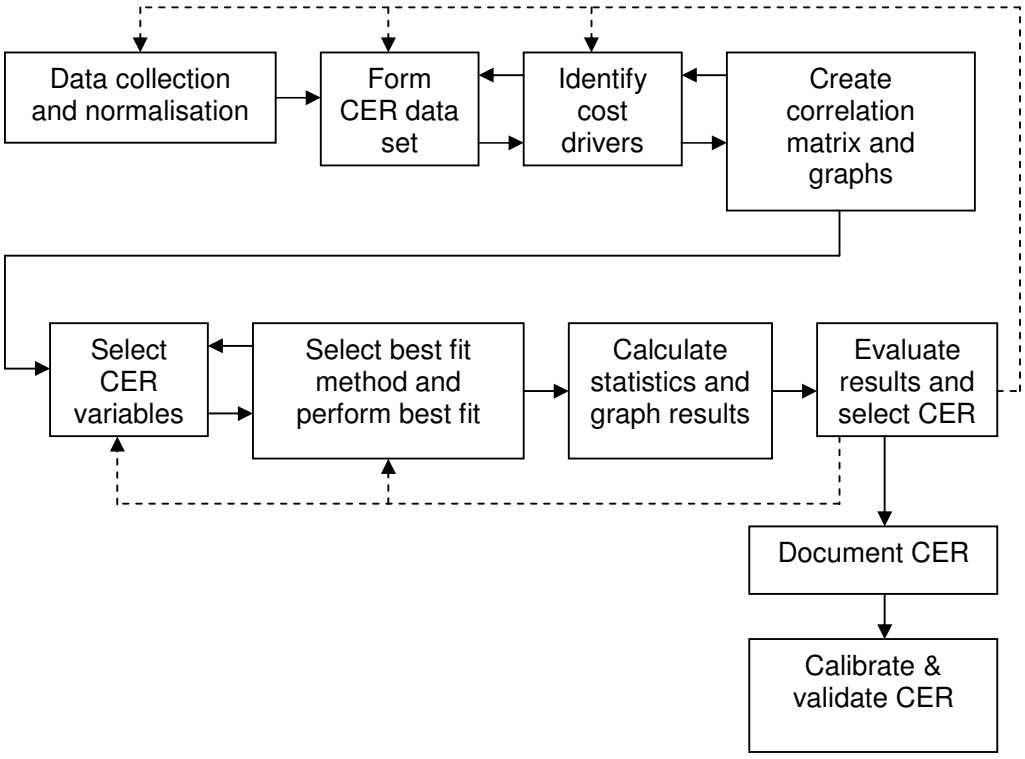

Figure 4.13: CER Development process

Source: SCEA, 2005: Appendix B, page 3

At the beginning of a cost estimating task lies the work breakdown structure (WBS), a list of everything that has to be paid to bring a system to its full operational capabilities (Kaiser, 2006: 255).

Classical least-squares regression (often referred to as "ordinary least squares" or "OLS"), developed by mathematicians in the 18th century, has in the past been the statistical procedure of choice in deriving CER's (Sonmez, 2004: 678). However, OLS has always imposed restrictions on an analyst who wants to derive functional relationships between dependent *y* and independent *x* variables, forcing him to model the error as additive when the relationship is linear ($y = a + bx$), logarithmic ($y = a + b\ logx$), or polynomialic, but as multiplicative when the relationship is exponential ($y = ax^b$) or power ($y = ab^x$) (SCEA, 2005: 3.5). "General-error regression", introduced some years ago to circumvent these problems, takes advantage of modern computing capability and advanced numerical analysis techniques, thereby offering the analyst the choice of optimising the CER's quality metrics by minimising additive or multiplicative error, regardless of the functional form of the relationship (Trost & Oberlender, 2003: 198).

4.0 IMPROVING CONCEPTUAL COST ESTIMATING PERFORMANCE

Conceptual cost estimating is a complex domain (Whiteside, 2004: EST.05.02) as it faces problems and restrictions. Zhang (2005: 4) and Zack (2006: 4) mention the need for continuous improvement in conceptual estimating. Whiteside (2004: EST.05.02) indicated that problems associated with estimating can be found in the following estimating functions:

- Scope definition,
- uncertainty evaluation and quantification,
- estimating generation and computing, and,
- estimate's expected accuracy and reliability assessment.

The first recognised characteristic of conceptual estimating is the fact that it is an inexact process based to a large degree on judgment and experience due to lack of information and the uncertainty at the conceptual stage (Kwak & Watson, 2005: 1430).

The experience of the estimator is probably the most important aspect when discussing conceptual estimate accuracy (Muscianesi, 2003: 2). Dysert (2005: 30) points out that the estimator studies construction projects undertaken by his company and while he is busy with these studies he acquires experience and knowledge which can be applied in conceptual estimating and which influence project cost performance. At the same time he becomes competent in carrying out the estimating function, leading to an improvement in estimating accuracy, especially if new projects are of the same kind and have the same characteristics as past ones. Yiu, Ho, Lo and Hu (2005: 108) studied the performance of estimators and found that experience allows estimators to better understand a new project based on previous ones, generate information that is not available by making sound assumptions, adjust existing knowledge and information according to current conditions, know where to look for relevant information and how to use it, and display other positive estimating capabilities.

When dealing with conceptual estimating, the estimator comes across two types of information – historical and current (Pickett & Elliott, 2007: EST.02.1). Of these two, historical is probably the most relevant. Information gives the estimator a reference from where to derive current cost figures. Lofton and Monteith (2004: EST.01.1) state that when estimating the cost of a current activity, actual data of previous similar activities is very helpful. However, data from previous activities must have enough visibility into the depth of the activity to be of use in producing estimates of similar depth. Getting this kind of information requires a suitable information system, capable of producing relevant estimating data (Rajpatty, 2008: DEV.12.2).

Having experience and information for conceptual estimating is useless if there is no processing system that applies these inputs to achieve the goal of determining the cost of the specific item (Perrott, 2004: EST.14.1). This system should provide greater consistency and accuracy to conceptual estimates. The processing system should support every conceptual estimating function. It must assist the estimator by offering advice when requested and by taking care of computing and offering the necessary values and answers (Kinney & Soubiran, 2004: EST.15.2). The idea is to have a system capable of emulating the performance of an experienced estimator (Muscianesi, 2003: 3).

4.1 Quality of conceptual cost estimating

For the decision maker, the quality of the conceptual cost estimate includes the expected accuracy and the reliability of the cost amounts provided by the estimate (Enshassi, Mohamed & Madi, 2005: 116). This estimate is carried out in a condition where an estimator has to determine an approximate value of the cost to accomplish a project based on a set of general information clues about what the project would be when finished. Some of these information clues include information on the project scope at the time of estimating, projected economic data, information about project technology and complexity, etc. (Chulkov & Desai, 2005: 140; Nassar & Hegab, 2006: 555). The quality and quantity of the clues will impact the capability of the estimator to accurately predict the cost of the future project (Trost & Oberlender, 2003: 202). Figure 4.14 demonstrates the level of accuracy of the estimate as time passes.

According to Boeschoten (2005: EST.20.2), the factors determining the accuracy and the reliability of conceptual estimates can be grouped into five major categories:

- scope quality,
- information quality,
- uncertainty level,
- estimator performance, and
- quality of the estimating procedure.

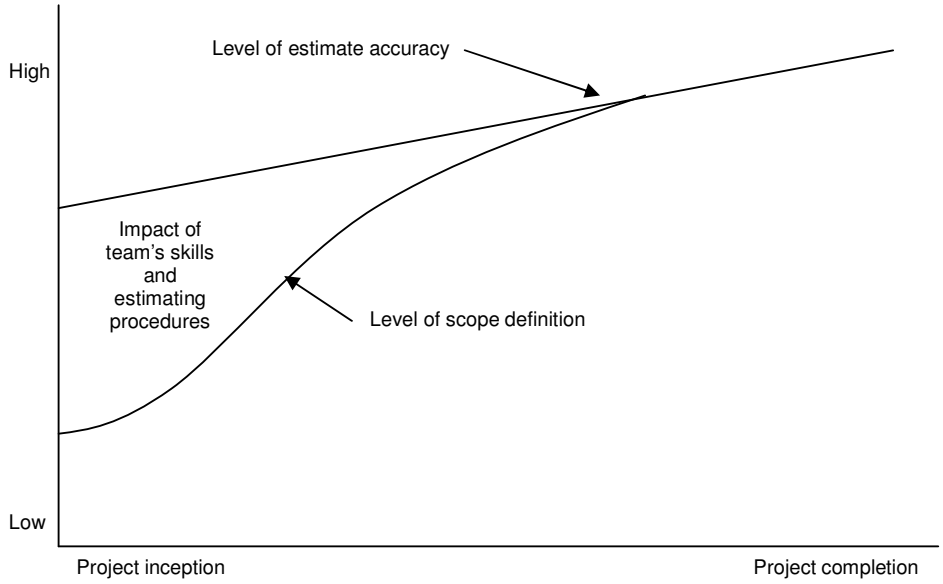

Figure 4.14: Estimate accuracy and project timeline
Source: Trost and Oberlender, 2003: 203

Generally each one of these categories implies adverse conditions for conceptual cost estimating. This means limited scope definition, restrictions of information, uncertainty of the construction project, insufficient experience available from estimators and significant errors or omissions (Kraus *et al.,* 2007: IT.01.1; Cheung, Wong, Fung & Coffey, 2008: 120; Ciccarelli & Murch, 2008: CDR.04.2). Improving these factors should lead to improving the accuracy of conceptual estimates. Table 4.10 shows a summary of factors affecting the accuracy and reliability of conceptual cost estimates. Using the information as indicated in Table 4.10, Serpell (2005: EST.13.2) developed an accuracy casual model for conceptual estimates as indicated in Table 4.11.

Recognising the importance of quality in conceptual cost estimates, the Construction Industry Institute (in America) formed the "improving early estimates research team" that investigated potential improvements (Serpell, 2005: EST.13.2). Serpell describes how the members of this team collected data of 67 construction projects around the world and identified 45 elements to measure the quality of early estimates. Among these there are 14 scope definition elements that could potentially impact the accuracy and 31 elements not directly related to scope definition, but that have the potential to influence the estimate's accuracy. Factor analysis and multivariate regression performed on the 45 elements identified five factors that exhibit a significant impact on an estimate's accuracy. Listed according to their significance, these five factors are as follows:

- scope definition,
- team experience,
- cost information,
- time allowed to prepare the estimate, and
- labour climate factor.

It is clearly established that a good scope definition is an imperative factor for the attainment of quality estimates (Gunner & Skitmore, 1999: 267). To obtain a high level of quality with a low level of scope definition and information, it is important to count on the estimator's experience. Serpell (2005: EST.13.2) points out that the influence of non-scope items on the estimate's accuracy over the life of a project may change as the project progresses from conceptual stage to completion. This statement was also proven by Trost and Oberlender (2003: 203). Figure 4.14 illustrates Trost and Oberlender's findings. This important need for experience at early stages also depicts

the reason why contingency is commonly assigned through experience (Gunham & Arditi, 2007: 495).

Scope	Information	Uncertainty	Estimator	Procedure
Quantities Definition Design approach State of design Completeness Detail Information quality Consistency Continuity Project nature Project technology	Processing Sought Availability Validity Completeness Relevance	Technology Project Environmental Productivity Market Construction Project nature	Talent/skills Experience Effort applied Expertise Judgment Knowledge Common sense Team ability	Mistakes Time available Measurements

Table 4.10: Summary of factors that affect the accuracy and reliability of conceptual cost estimates

Source: Serpell, 2005: EST.13.2

The availability of time to prepare the estimate is also an important factor. It is a well-known fact that progressive development of information technology tools is currently reporting remarkable benefits, i.e. improvements for design, procurement and construction for different sectors of the construction industry (Warszawski, 2003: 423)..

Figure 4.15 depicts an idealised picture of a cost forecasting programme. This figure indicates that at any point of a project's life, there are four elements of cost. The undefined elements, implied by the scope, can be covered by the contingency. Figure 4.15 shows the relationship of these four elements over time. Gradually, as the project progresses, the contingency, escalation and project growth become defined elements. At the end of the project the defined elements represent all costs, having replaced the other three completely (Boeschoten, 2005: EST.20.2).

4.2 Assessing the quality of conceptual cost estimating

Assessing or predicting the expected accuracy of an estimate is a difficult problem with no clear solution, a common characteristic of most prediction or forecasting problems (Park *et al.,* 2005: 164). Serpell (2005: EST.13.4) indicates that there are two basic categories of predicting methods that can be considered for assessing estimate quality:

- Data-based methods: Forecasts are made using historical data and quantitative models.
- Judgmental-based methods: Individual opinions are acquired and processed to derive predicted values.

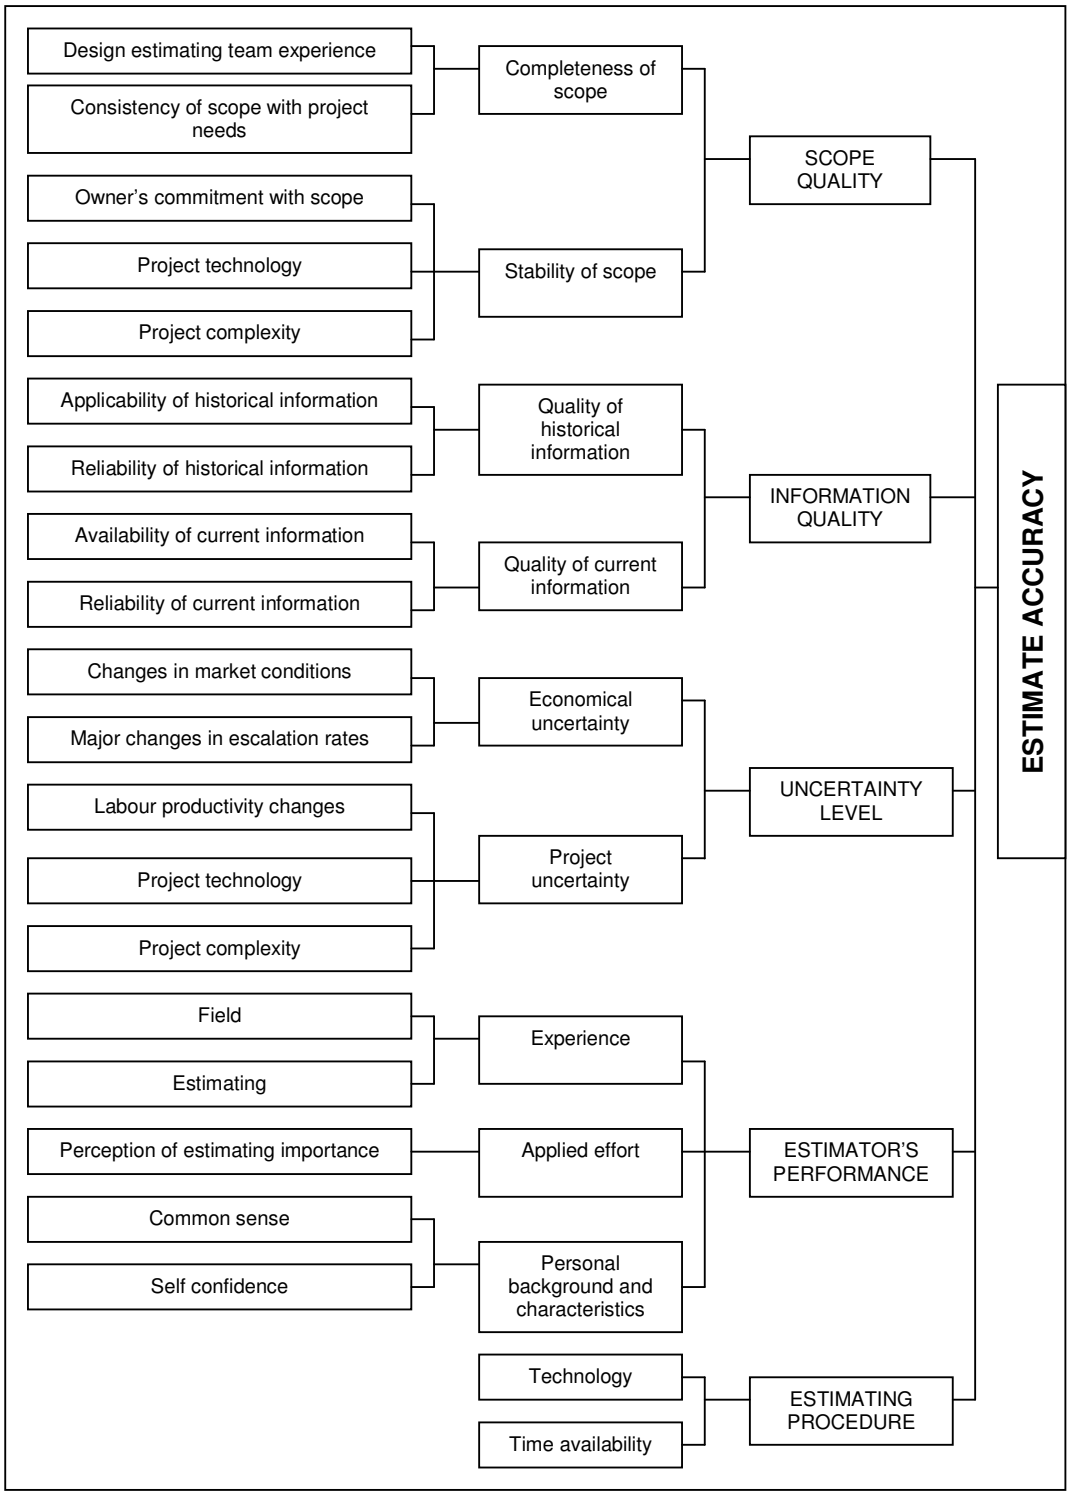

Table 4.11: Factors that affect the accuracy of conceptual cost estimates

Source: Serpell, 2005: EST.13.3

The data-based methods would require the availability of historical accuracy performance of estimate data and to use this data to predict future outcomes. This approach ensures that what happened in the past is applicable to similar situations in the future (Kaka, 1999: 260). Using the data-based approach, extrapolative or casual models can be used for predicting the future. Although these methods are well known and are used in many real situations, the assessment of estimate quality presents several limitations that preclude their application in this case (Serpell, 2005: EST.13.4).

The judgment-based approach corresponds to the acquisition and processing of individual or group opinions, normally from experts in the field of interest (Wilont & Cheng, 2003: 273). In this case experts have to assess the values of some critical variables looking at the value of the factors that impact them, using qualitative models, like the accuracy factor model. However, prediction models that use judgment also have some disadvantages for estimate quality assessment (Williams, 2005: 40). These disadvantages can be described as follows:

- They are difficult to validate because of the lack of hard data.
- They are subject to expert biases that can greatly reduce their efficiency.
- Their performance can be worse than the performance of quantitative methods in many cases.

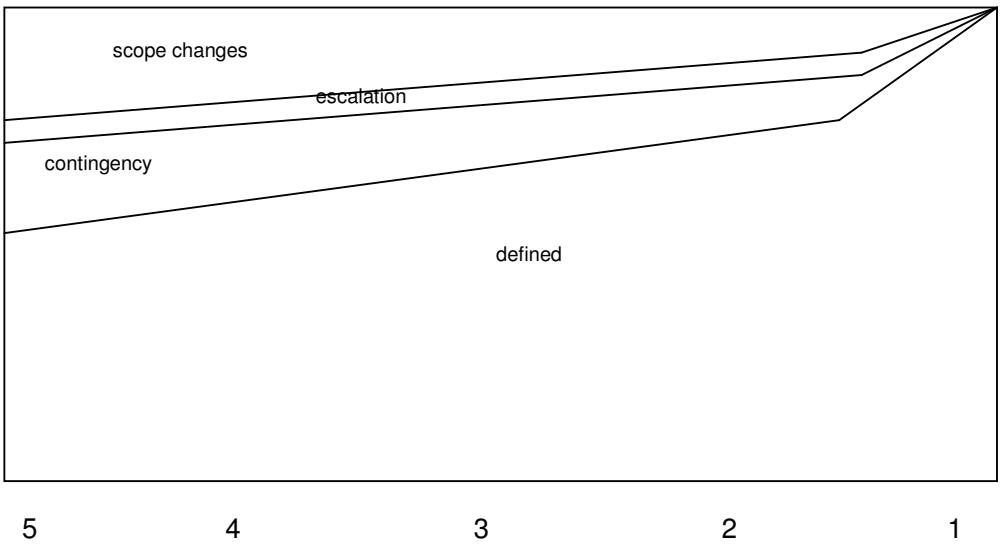

Figure 4.15: The relationship of scope changes, escalation, contingency and defined scope during the course of the project

Source: Boeschoten, 2005: EST.20.3

Although these limitations are important, they are offset by the more restrictive limitations faced by the data-based methods. Also, the complexity of the problem makes it more difficult to use a quantitative orientated model. Only when conditions are similar in practice can more accurate predictions using quantitative techniques be expected (Hua, 2008: 488). When the estimator is dealing with a limited number of observations, qualitative methods might be more appropriate (Vilela & Longo, 2008: INT.11.1). Unal, Keeting, Chytka and Conway (2005: 36) indicate that on average judgmental and quantitative predictions are equally accurate, while in certain circumstances judgmental predictions are significantly better. Al-Tabtabai, Kartam, Flood and Alex (1997: 273) had similar findings.

Fayek and Oduba (2005: 938) state that the proposed methodology is primarily based on experts' experience and judgment that can be complemented and expanded with feedback information generated after each project. This information will serve to validate experts' assessments, to correct biases of experts' assessments and to generate more objective assessment models (Al-Tabtabai *et al.,* 1997: 274).

The assessment of experts is based on the accuracy casual model illustrated in Table 4.11. Two simplifications are introduced in this model. First, due to the subjective nature and the difficulty of assessing the factors that impact the estimator's performance, it has been assumed that this can be considered a constant value (Yiu *et al.,* 2005: 109). This assumption will be reinforced if the estimator has a conceptual estimating system supported by information technologies. A computer based estimating system would also minimise or even eliminate the possibility of procedural and calculation errors and significantly reduce the time pressure (Karshenas, 2007: IT.06.1; Richards, 2005: EST.12.1). The quality of the estimating procedure can then be assumed to be constant (Masmoudi *et al.,* 2005: 300).

Karshenas (2007: IT.06.1) indicates that computer based estimates are based on the application of expertise and knowledge through a knowledge-based expert system approach. According to Serpell (2005: EST.13.5), the development of this assessment methodology requires the solution of the following problems:

- Determination of the assessment reasoning procedure.
- Acquisition of assessment knowledge.
- Representation of knowledge.

- Combination of experts' assessments.
- Determination of estimate reliability.

The assessment reasoning procedure has been designed to evaluate the quality of an estimate by providing a qualitative reasoning approach. Table 4.12 displays a general flow diagram of this procedure. Serpell (2005: EST.13.5) states that the first step in this procedure is to determine the conditions of the new project. These conditions correspond to the values on the most detailed level factors or raw factors of the model depicted in Table 4.11. They are determined by the user as he appraises the different factors for the project/estimate under study. The set containing all these values establishes the scenario under which the cost of the project is estimated (Serpell, 2005: EST.13.5).

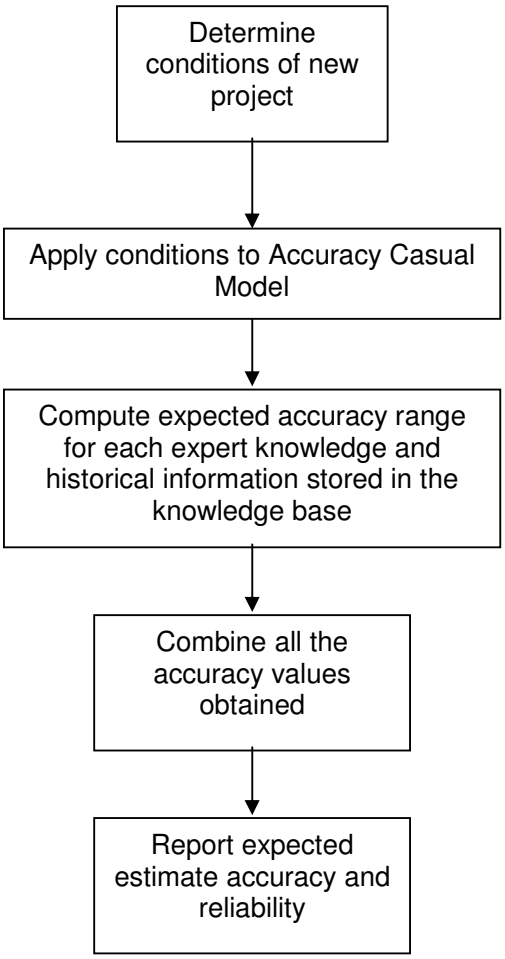

Table 4.12: Conceptual estimate quality assessment procedure

Source: Serpell, 2005: EST.13.4

Scope
Improve scope definition process (make it quickly and control changes).
Practice use of scope estimating.
Work with clients to make them understand what data is important for accuracy.
Develop a good understanding of clients' and designers' culture and philosophy.
Develop computer programmes to analyse a project and identify its parts from limited detail.
Get a written scope definition.
Spend more time and money in the definition phase.
Information
Keep better historical records.
Use computer programmes with quantitative inputs and historical data bases.
Improve feedback mechanisms.
Assure the availability of day-to-day cost data and systems.
Improve the availability of information.
Create a database for trends and rules.
Estimating
Incorporate risk management tools for estimating.
Develop better cost factors for estimating.
More case study about problems and successes.
Make more realistic assumptions.
Develop team work attitudes with owner and designer at early stage.
Develop checklists for items normally included in projects.
Develop a range of factors (worst to best cases) for components.

Table 4.13: Recommendations for improving conceptual cost estimating
Source: Serpell, 2005: EST.13.5

For accuracy assessment it is important to note the characteristics of the construction industry and the estimator's experience relevant for this problem. These characteristic are:

- Estimating expertise is specialised, normally by type of project and sometimes at even more specific levels (Fayek & Oduba, 2005: 938). As a

result of this, estimators are most of the time strongly biased in their assessments because they try to relate their experience in every case, even if they are assessing a totally different kind of project.

- It is very common that companies that construct similar kinds of projects approach estimating in very different ways. Also, the general attitude of the company's estimating team toward risk can be different. These two factors add new biases to the accuracy assessments.
- The lack of sharing of estimating information between companies in the construction industry contributes to the non-availability of global estimating data to perform assessments at this more general level.

Table 4.13 provides some recommendations for improving conceptual cost estimating in general.

5.0 SUMMARY

Conceptual estimates are generally based on scant project information. The accuracy of these estimates can depend on several factors such as the level of project definition, the quality of the past historical data and development of factors and algorithms, as well as judgment and experience of the estimator. These limitations impede on the accuracy of the conceptual estimating process. Conceptual estimates can, however, be quite reliable, especially in estimating repeat projects. Generally, the emphasis with conceptual estimates is not on detailed accuracy, but on obtaining a reasonable cost estimate of sufficient accuracy to ensure that the results are meaningful for management to make investment decisions.

The basic process in developing a conceptual estimate can be summarised as follows:

- Develop an estimating plan.
- Develop major equipment costs (MEC).
- Apply factored costs.
- Develop quantified costs.
- Develop indirect costs.
- Analyse risks, apply contingency and finalise estimate.

The assessment of project risks is probably the most important step in conceptual cost estimating. The allocation of costs to allow for risk can be done through an allowance for escalation as well as an allowance for a contingency. Specifics of these allowances follow in Chapter 6 of this study.

Some of the more well-known conceptual cost estimating procedures include the following:

- Probabilistic cost estimation.
- Ratio conceptual estimating.
- Regression analysis.
- Neural network analysis.
- Parametric estimating.

Irrespective of the type of conceptual estimate used, a good quality cost database will always be a requirement and the best way to improve conceptual cost estimates will always be to improve the cost database first. Other problems associated with estimating can be described as follows:

- Scope definition.
- Uncertainty evaluation and quantification.
- Estimating generation and computing.
- Estimate's expected accuracy and reliability assessment.

It is a good starting point to realise that the conceptual estimate is an inexact process and is to a large degree based on judgment and experience due to a lack of information during the early stages of the project.

The main difference between a conceptual estimate and a detailed cost estimate is that most of the work and effort to obtain a conceptual estimate is done before the estimate actually starts. With a detailed estimate most of the work is done only when specifications and drawings from the engineer have been received, making it a much longer process. As conceptual estimates are based upon historical data of past projects, considerable time will be spent to keep databases up to date and as accurate as possible. The following chapter comments on the importance of the historical database and how it is applied.

CHAPTER 5

DATA COLLECTION AND ANALYSIS

1.0 INTRODUCTION

Data collection and development for conceptual estimating require a significant effort. The quality of the resulting model can be no better than the data it is based upon. Both cost and scope information must be identified and collected. The level at which the cost data is collected will affect the level at which the model can generate costs, and may affect the derivation of the CER's (Cost Estimating Relationship) (Dysert, 2008: EST.03.2).

Cost data should be collected at a fairly high level of detail. The data can always be summarised later should an aggregate level of this information provide a better model (Martin, 2004: IT.02.1). The scope information should include all the proposed design parameters or key cost drivers for the model, as well as any other information that may affect costs (level of complexity, schedule type, etc.). The type of data to be collected usually is decided upon in coordination with the engineering and project control communities. Evrenosoglu (2008: CDR.16.1) recommends the creation of a formal data collection form that can be used consistently and revised if necessary.

After the data has been collected, it must be normalised before it can be analysed. Normalising the data refers to making adjustments to the base cost data to account for the differences between the actual basis of the data for each project, and a desired standard basis of data to be used in the estimating model (Musgrove, 2008: EST.07.2).

Typically data normalisation implies making adjustments for escalation, location, cost scope, site conditions, and system specifications. Costs for historical projects should be adjusted to common time frames and common locations serving as the standard basis for the model (Assiskumar, 2008:EST.16.1). Normalising for cost scope implies making adjustments for the unique scope that a specific historical project incurred but that is not included in the standard basis for the model.

Data analysis consists of performing regression analysis of costs versus selected design parameters to determine the key cost drivers for the estimating model (Kaka,

1999: 257). Reasoned hypotheses or expert opinion might be employed to identify and test the best cost drivers. The use of mathematical functions is a time-consuming process that takes some experimental efforts to determine the best possible result.

Good data underpins the quality of any estimating system or method. As the acquisition community moves towards estimating methods that increase their reliance on historical costs, the quality of the data cannot be taken for granted. Industry should find methods to establish credible databases that are relevant to the history of the specific organisation in question (Martin, 2004: IT.02.1). From this the estimator will be in a better position to reliably predict future costs.

2.0 DATABASE REQUIREMENTS

Taking advantage of lessons learned from past experiences and using this information to the estimator's benefit will give him an edge over his competitors when estimating future work (Pickett & Elliot, 2007: EST.02.1). Using historical project data to help make strategic business decisions can play a significant role in improving the competitiveness in the market (Shah *et al.,* 1996: 347). Historical data can assist in making decisions as to which projects are more favourable to undertake. It is therefore important that information be available to improve estimating, scheduling and control of future capital projects.

The world economy and domestic markets play an important role in the petrochemical industry, dictating to a large extent the construction of new plants. As work decreases, the availability of historical data also tends to decrease, probably because of the non-availability of resources (Shah *et al.,* 1996: 347). As times improve, more plants are constructed which lead to an increased availability of historical data which can be used in estimating and benchmarking of projects. Therefore future work cannot be improved if historical data is not analysed (Shah *et al.,* 1996: 348).

Resolving database problems to meet user needs is not an easy task. For example, cost analysis methodologies may vary from one analysis or estimate to the next and the data or information requirements for Cost Estimating Relationships (CER's) may not be constant over time. The current data requirements do not determine future needs as well, and should be periodically reviewed (Evrenosoglu, 2008: CDR.16.2). The routine maintenance and associated expense should always be a consideration.

An outdated database is of little use when forecasting future acquisition costs (Assiskumar, 2008: EST.16.1).

Pickett and Elliot (2007: EST.02.1) refer to the lack of sufficient data over the past 25 years in the Canadian construction industry due to a lull in activities in this market. In their opinion, this is largely due to an exodus of experience and an unwillingness of management to recognise database development as a necessity and not an unnecessary overhead. Pickett and Elliot (2007: EST.02.1) also refer to cost overruns on a range of projects in recent history in the Canadian sector which sparked an increased development of databases as the importance of such databases was reiterated. Lowe and Skitmore (2001: 490) point out that this has driven the need for greater upfront analysis of project cost and schedules. Many companies are realising that much more focus is needed in the area of benchmarking and the development of associated historical metrics that can be used to validate future projects (Assiskumar, 2008: EST.16.1).

Before beginning the data collection process, certain methodologies and systems (or enablers) must be put in place. Musgrove (2008: EST.07.2) mentions that one of the most important of these enablers is obtaining management support. Not only must company management support historical project data collection, they must understand and actively promote this effort as well. Many resources across the entire company hierarchy will be relied upon in order to retrieve and collect this data. Some other important enablers are:

- Personnel: Perhaps as important as management support, there should be well-trained staff to whom to entrust the database development. Lucena (2006: 321 – 322) indicates how engineering experience can influence the success of a project.
- Infrastructure: Regardless of what method is used to collect the data, a minimum infrastructure of networking capabilities and computer applications will be required to successfully support the database (Mähring, Holmström, Keil & Montealegre, 2004: 211; Moussourakis & Haksever, 2007: 601).
- Code of accounts: When attempting to collect project cost data, there must be a systematic method of categorising this information. In order to do this, most companies (whether the owner or contractor), will use a standard structure most often referred to as a code of accounts (Kohl & Wulke, 2004: IT.03.1). In layman's terms, the code of accounts represents a coded index

of project costs, resources and activity categories where codes are used to summarise, categorise and manage project information. The code of accounts has been discussed in more detail previously in this study.

- Cost control system: Establishing a code of accounts will be followed by ensuring that there is a means of capturing and storing estimated and actual project costs and resource data. Once there is an operational cost control system in place, it must be capable of collecting and reporting costs using the predefined code of accounts (Al-Jibouri, 2003: 144). Only then can costs be rolled up into the proper categories which will facilitate the transfer of data to the historical system.

3.0 COLLECTION OF ACTUAL PROJECT DATA

Conceptual estimating techniques require the collection of historical cost data and the associated non-cost information and factors that describe and strongly influence those costs (Kinney & Soubiran, 2004: EST.15.1). Martin (2004b: IT.02.2) points out that data should be collected and maintained in a manner that provides a complete audit trail with expenditure dates so that costs can be adjusted for inflation. While there are many formats for collecting data, one commonly used by industry is the Work Breakdown Structure (WBS), which provides for the uniform definition and collection of cost and certain technical information (Verveniotis, 2008: PM.02.1).

As mentioned, the establishment of the prerequisites will lead to the collection and normalisation of project data (Musgrove, 2008: EST.07.2). Standard project cost collection forms should be developed to capture data. Refer to Addendum B within this study as a standard sheet to be used for this purpose. As mentioned previously, the historical database serves an important purpose in deriving a budget for projects at an early stage of their development, as well as in the validating of estimates for new work. Assiskumar (2008: EST.16.1) indicates that almost every company in the construction business tracks down their own cost information in a format suited to their practice and needs.

Various factors play a key role in interpreting the data. Some of these include the size of the project, year being built, inflation rate, local market conditions, complexity of the project, procurement method, site conditions, etc. (Kuprenas & Nasr, 2007: 114; Shash, Assaf & Jannadi, 2007: 18). Hereafter follows a short discussion of the influences on costs of any given project that will be reflected in the collected data.

The collection point for cost data is generally the company's management information system, which in most instances contains the general ledger and other accounting data. All data used in conceptual estimating techniques should be consistent with, and traceable to the collection point. The data should also be consistent with the company's accounting procedures and generally accepted cost accounting practices.

Technical non-cost data describe the physical, performance and engineering characteristics of a system, sub-system or individual item. For example, weight is a common non-cost variable used in CER and parametric estimating models (Polla, 2007: 14). Other examples of non-cost drivers are horsepower, watts, thrust, etc. A fundamental requirement for the inclusion of a technical non-cost variable in a CER is that it must be a significant predictor of cost (Edwards, Holt & Harris, 1998: 25). Technical non-cost data comes from a variety of sources including engineering drawings, engineering specifications, certification documents and interviews with technical personnel (Postavaru, 2004: 3).

Once collected, cost data must be adjusted to account for the effect of certain cost factors such as production rate, improvement curve and inflation (Kallantzis, Soldatos & Lambropoulos, 2007: 485). This process is referred to as data normalisation. Relevant programme data including development and production schedules, quantities produced, production rates, equivalent units, breaks in production schedules (Khosrowshahi, 1997: 255), significant design changes, (Lee, Park & Cho (2007: 159), and anomalies such as strikes, explosions and other natural disasters are also necessary to fully explain any significant fluctuations in the data. Such historical information can generally be obtained through interviews with knowledgeable programme personnel or through examination of programme records (Arnold & North, 2008: 104).

3.1 Work breakdown structure (WBS)

A work breakdown structure is a tree-like structure that permits summing of subordinate costs for tasks, materials, etc. into their successively higher "parent" tasks, materials, etc. (Gordon, 2008). For each element of the work breakdown structure, a description of the task to be performed is generated. Biffi (2008: TCM.02.2) refers to a work breakdown structure as organised around the primary products of the project. As previously stated this means that the work breakdown structure is organised around

the planned outcomes rather than planned actions (Kauffmann, Keating & Considine, 2000: 13). Chapter 3 contains some general information on the WBS.

The term Work Breakdown Structure (WBS) is defined by the Department of Defense (2005: 5) in terms of aircraft weapon systems as:

a. A product-oriented family tree composed of hardware, software, services, data, and facilities. The family tree results from systems engineering efforts during the acquisition of a defense material item.

b. A WBS displays and defines the product, or products, to be developed and/or produced. It relates the elements of work to be accomplished to each other and to the end product. In other words the WBS is an organised method to breakdown a product into sub-products at higher levels of detail.

c. A WBS can be expressed down to any level of interest. Generally, the top three levels are sufficient unless the items identified are high cost or high risk. Then is it important to take the WBS to a lower level of definition.

Refer to Chapter 3 for more generalised definitions of a WBS. Figure 5.1 demonstrates a typical WBS evolution. This WBS evolution illustrates how a WBS would evolve on a typical development project. The Department of Defense (2005: 9) suggests this evolution model for WBS when dealing with defense contracts. This model can also be used when plotting any WBS in a particular project.

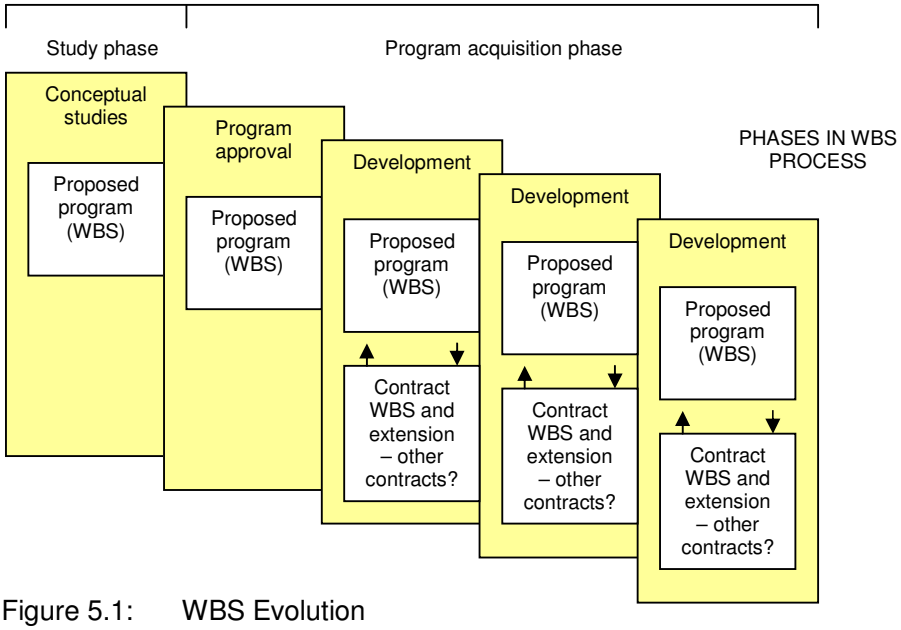

Figure 5.1: WBS Evolution

Source: Department of Defense, 2005: 9

3.2 Data sources

Kinney (2006: EST.21.1) states that the specification of an estimating methodology is an important step in the estimating process. The basic conceptual estimating methodologies are all data driven (Kinney & Soubiran, 2004: EST.15.1). Credible and timely data inputs are required to use any of these methodologies. Table 5.1 shows nine sources of data, and also whether they are considered a primary or a secondary source. Primary data sources will attract the most attention from the estimator.

Primary data is obtained from the original source and considered to be the best quality and the most reliable (Park & Peña-Mora, 2004: 630). Secondary data is derived from primary data, and is therefore not obtained directly from the source. Because of this, this form of data might be of lower overall quality or usefulness (Melamed *et al.,* 2007: RISK.06.2). The collection of the data necessary to produce an estimate and its evaluation for reasonableness is critical and often time-consuming. Collected data include cost, programme and technical and schedule information because these programmatic elements drive costs (Thurlow, 2009: 30 September). The bottom line is that the cost analyst and estimator are not solely concerned with cost data – they need to have technical and schedule information to adjust, interpret and support the cost data being used for estimating purposes.

A cost estimator has to know the standard sources of historical cost data. This knowledge comes both from experience and from those people capable of answering key questions (Van der Werf, 2004: EST.07.2). A cost analyst or estimator should constantly search new sources of data.

Musgrove (2008: EST.07.3) states that some sources of data may be external. These include databases containing pooled and normalised information from a variety of sources (Harris, 2004: CDR.13.1). Although such information can be useful, it may have the following weaknesses:

- No knowledge of the manufacturing and/or software processes used and how they compare to the current scenario being estimated (Vits, Gelders & Pintelon, 2007: 5).
- No knowledge of the procedures used by other contributors.
- No knowledge of the treatment of anomalies in the original data.
- The inability to accurately forecast future indices (Yu & Ive, 2006: 788).

Sources of data	
Source	Source type
Basic accounting records	Primary
Cost reports	Either (Primary or secondary)
Historical databases	Either
Functional specialist	Either
Technical databases	Either
Other information systems	Either
Contracts	Secondary
Cost proposals	Secondary

Table 5.1: Sources of data
Source: SCEA, 2005: Appendix B page 5

3.3 Type of data to be collected

Stenzel and Stenzel (2003: 2) define cost as follows:

> "*Cost is an outflow of a resource, whether in cash, as a payable, a rendered service, or a trade or barter that is consciously made with expectation of benefit to the organisation: goods, property, or service required."*

The estimator needs costs to complete his estimate and to submit a competitive price into the market. Especially in the case of conceptual estimates, it will be necessary to rely on data that support the above definition of cost, to enable the estimator to build a meaningful estimate.

3.3.1 Project description and scope

A clear description of the project scope (Sharma & Lutchman, 2006: EST.16.1) will enable the estimator to produce an effective estimate in the sense that similarities between plants or portions of plants can be identified more easily (Sonmez, 2004: 678). Technical data such as plant density, heights of structures, type of material used, access restraints, etc. will have to be stated.

3.3.2 Size of project

Economies of scale suggest a direct relation between the size of a project and the cost thereof (Shash *et al.,* 2007: 19). Larger projects will cost more than their smaller counterparts, but the individual unit rates for different sections will be less than that of a smaller project (Ashworth, 2004: 23; Cha & O'Connor, 2005: 241). It is therefore important to note the size of the project to make this adjustment.

3.3.3 Location and local market conditions

Martin (2004b: IT.02.1) comments that the construction industry is one of only a few industry types where the "production factory" is constantly moved to a different location according to where the next project is situated. Jansen-Rommijn (2008: EST.13.1) states that the work does not come to the factory, the factory goes to the work, and in most cases, to different locations. Oladapo *et al.,* (2008: 118) discuss the importance of

location adjustment factors. This makes dealing with the challenges of location difficult and almost every project is unique in this sense. Some of the considerations that will influence cost due to different locations and market conditions can be tabulated as follows:

- Added cost for transportation.
- Availability of skilled labour.
- Local labour union restrictions.
- Local by-laws and regulations and standards.
- Accessibility to other facilities.
- Security concerns.
- Safety and environmental considerations (Karam & Venter, 2007: 36).

3.3.4 Site conditions

Site conditions with respect to access, proximity of other structures and construction difficulties related to topographical, geological and climatic conditions are to be investigated (Deschenes & Greenstone, 2007: 355; Kaiser, Pulsipher & Martin, 2005: 120). As far as the season is concerned, winter construction is more expensive (Assisskumar, 2008: EST.16.3) and may cause costly delays. Production is less during winter time, especially in countries where extreme cold is experienced (Lapidow, 2007: 45 – 46). Nogueira and Paixão (2007: 455) indicate similar difficulties associated with locations where extreme heat occurs in summertime. Should the project be constructed in more favourable climatic conditions and at a different time of the year, less labour availability (O'Mahony, Robinson & Vecchi, 2008: 1438), increased cost of equipment such as scaffolding, etc. can be experienced due to the increased construction activities (Shapira & Goldenberg, 2007: 750; Shapira, Lucko & Schexnayder, 2007: 692).

3.3.5 Year of construction

The year in which the project is being constructed is important for two reasons, the first being the adjustment for escalation (inflation) to normalise the data to a common base and the second to identify specific market spikes that occurred in that year (Touran & Lopez, 2006: 855). The price of steel can, for instance, increase abnormally during a specific year which will lead to a market panic, causing contractors and sub-contractors

to increase prices by more than the suggested escalation to counter similar market movements during the construction phase of the project (Hagmann, Stoy & Terashima 2008: INT.07.2).

3.3.6 Overhead and profit

Ibbs and Nguyen (2008: 32) and Enshassi, Aziz and Karriri (2008: 38) point out that different sentiments exist regarding overhead and profit application to the general project cost. Normally, the smaller the project, the greater the percentage of overhead costs and profit (Ikpe, Potts, Proverbs & Oloke, 2007: PM.12.1). If data from other companies or sources are being used, the estimator should make sure that he understands the conditions as to which overheads and profit have been applied to. This will enable him to normalise the data to a common base (Dieterle, 2008: CDR.10.3).

3.3.7 Complexity of work

Jiao and Tseng (1999: 739) comment on the effect of the use of standard construction methodology versus that of non-standard methods. A great deal of process plant work can be considered as standard type construction work. Most clients make use of similar specifications and most clients have similar safety requirements and hold points (mandatory stoppage to allow inspection to take place) for inspections (McCarthy, 2004: 8). Should this not be the case, the estimator will have to adjust the data to allow for these additional costs. Pickavance (2008: CDR.15.1) discusses the effect of complex contracts and contract claims. A generalised discussion with the construction manager of a given project will reveal most of the information needed to make the necessary adjustments.

3.3.8 Procurement method

Contractor and consultant selection and appointment play an important role in the costing of the overall project. The type of contract used can also influence that ultimate pricing structure (El Wardani, Messner & Horman, 2006: 231). For instance, the implementation of the New Engineering Contract (NEC) in recent years caused uncertainties within the industry that influenced prices. The very nature of this contract is such that more resources are required to fulfill the contract's obligations which will also lead to increased costs. Procurement may also have an effect on project costs when specialised work is conducted (Leadre, Austeng, Haugen & Klakegg, 2006: 692).

In many cases, there are limited numbers of contractors/consultants to perform this type of work that may lead to abnormalities in pricing (Kuprenas & Nasr, 2007: 114).

3.4 Data normalisation

Data normalisation reduces inconsistencies and anomalies within the data. Data normalisation was also discussed in Chapter 4 of this study. Assiskumar (2008: EST.16.2) states that data must be adjusted to eliminate any bias or "unevenness" which other factors may have caused. This is referred to as normalisation and is intended to make the data set homogeneous, or consistent. The analyst should evaluate each data set and make sure that it is free from the effects of:

- the changing value of money over time,
- cost improvement as the organisation improves its efficiency over time,
- various production quantities and rates during the period from which the data were collected.

Figure 5.2 depicts the data normalisation process flow. This figure does not describe all activities in detail, but it does provide an illustration of the primary activities in data normalisation.

The first step in the normalisation process is to weed out any projects where the data is deemed to be unusable (Evrenosoglu, 2008: CDR.16.2). The following are some reasons why data might not be acceptable:

- Deviant accounting and/or project controls.
- Too small project.
- Direct equipment purchase (where the crux of the contract is mainly for equipment or material procurement).
- Ad hoc projects (where certain portions of the project are of a "once-off" nature making the data suspect since it cannot be considered to be the norm).

After removing the projects or portions of projects that should not be used in the database, the data should further be altered to make it comparable (Martin, 2004b: IT.02.2). The following steps will normally apply:

- Making the units of cost consistent.
- Making the year of economics consistent (common time frame).
- Account for missing cost items if possible.
- Remove cost items that are not applicable.
- Assigning a project classification.

3.4.1 Inflation adjustments

Inflation is defined as the rise in the general level of prices, without a rise in output of productivity (Karpetis, 2008: 208). There is no fixed way to establish universal inflation indices (past, present and future) that fit all possible situations. Inflation indices generally include internal and external information and factors (Faig & Jerez, 2006: 3). The Consumer Price Index (CPI) and Production Price Index (PPI) are examples of just two external factors that will influence inflation (Flemming & Koppelman, 2009: 22).

Inflation indices should be based on the cost of materials and labour on a unit basis and should not include other considerations such as manpower loading, or the amount

of materials used per unit of production (Hamood Al-Harthy, 2007: 280). The key to inflation adjustments is consistency. If cost is adjusted to a fixed reference date for calibration purposes, the same type of inflation index must be used in escalating the cost forward or backwards from the base date, or the date of the estimate (Lum, 2004: 32). More information on escalation and the effect thereof will follow in this study.

3.4.2 Cost improvement curve (learning curve)

Wong *et al.,* (2007: 476) point out that when first developed, cost improvement was referred to as "learning curve" theory, which states that as the quantity of a production item doubles, the manufacturing hours per unit expended producing it decrease by a constant percentage. The learning curve, as originally conceived, analysed labour hours over successive production units of a manufactured item, but the theory behind it has now been adapted to account for cost improvement (Zheng, Ng & Kumaraswamy, 2005: 82). Both cost improvement and the traditional learning curve are defined by:

$$Y = AX^b$$

Where:

Y = Hours per unit
A = First unit hours
X = Unit number
b = Slope of the curve related to learning

There are two interpretations concerning the application of this equation. In the unit interpretation, Y is the hours or cost of unit X only. In the cumulative average interpretation, Y is the average hours or cost of all units from 1 to X, inclusive. More information on the cost improvement curve was presented in Chapter 4.

3.4.3 Production rate

Mountney, Gao and Wisealls (2007: 1522) define the production rate as the number of items produced over a given period of time. The improved equation below modifies the basic formula to capture changes in production rate (Q^r) and organisational cost improvement (X^b):

$Y = AX^b Q^r$

Where:

Y = Hours per unit
A = First unit hours
X = Unit number
b = Slope of the curve related to learning
Q = Production rate
r = Slope of the curve related to the production rate

This improved equation is generally applicable when there is substantial production at various rates. The production rate variable (Q^r) adjusts the first unit dollars (A) for various production rates during the life of the production effort. The equation also yields a rate-affected slope relating to learning.

3.4.4 Consistent scope

Song and AbouRizk (2005: 362) suggest that only data of projects with similar scopes should be compared. If the scopes do not correspond, modifications should be incorporated to adjust the data to make the scopes comparable.

3.4.5 Anomalies (unusual events)

Historical cost data should be adjusted for anomalies when it is not reasonable to expect the new project estimates to contain these unusual costs (Kaka, 1999: 259). The adjustments and judgments used in preparing the historical data for analysis should be fully documented. Perfect cost data may not exist, but good judgment and analysis should supply reasonable results (Pickett, 2005: EST.10.3).

A contractor should use historical data and his estimating system should provide for the identification of source data and the estimating methods and rationale used to develop an estimate (Poh, Malcolm & Horner, 1995: 125). Therefore, all data, including any adjustments made, should be thoroughly documented by the contractor so that a complete trail is available for verification purposes. Pickett & Elliott (2007: EST.02.3) indicated some key questions that should be asked during the review of data collection and analysis include:

- Is sufficient data available to adequately develop parametric techniques?
- Has the contractor established a methodology to obtain, on a routine basis, relevant data on completed projects?
- Is cost, technical and programme data collected in a consistent format?
- Will data be collected in a manner that is consistent with the contractor's estimating practice?
- Are procedures established to identify and examine any data anomalies?
- Was the source data used as is, or did it require adjustment?
- Are adjustments made to the data points adequately documented to demonstrate that they are logical, reasonable and defensible?

4.0 IMPLEMENTATION OF A HISTORICAL DATABASE SYSTEM

With sufficient project cost and schedule information available, an automated system can either be purchased or developed to contain all the historical information (Musgrove, 2008: EST.07.3). This system will contain a database of historical project cost, schedule, resource and technical data from completed projects and should be capable of generating presentation reports. The goal of the project historical database system is to collect data and convert it into a strong knowledge base that can be used to drive improvements throughout the project process (Martin, 2004b: IT.02.3; Kaka, 1999: 257). It is also generally acknowledged that companies that use historical database systems can improve their overall project performance over a period of time.

Implementing a project historical database system will allow a company to provide the following:

- Cost estimate validation for formal estimate reviews.
- Generation of key benchmark data for estimate reviews.
- Cost estimate database calibration information.
- Front-end or strategic level cost estimates.
- Strategic level scheduling information.

The data contained in the historical database system can be used for various purposes, as described above. Martin (2004b: IT.02.3) indicates that the primary goals will be to improve current practices relating to estimating, cost control, strategic scheduling and standard project processes. This can be done by converting the

historical project data into a useful knowledge base that can identify deficiencies and highlight areas for improving the overall project performance (Kaka, 1999: 257). Some of the most important contributions of the historical database are as follows:

- Benchmarking: One of the primary benefits of the project historical database is to provide benchmarking data and factors that will be an invaluable aid for reviewing and validating estimates (Chan & Chan, 2004: 210). The estimate review should include a benchmarking report that compares ratios and factors from the estimate being reviewed with historical values from similar types of projects in the database.
- Database calibration: In addition to providing benchmark data for estimate reviews, the historical data that was collected can also be used to check and calibrate the estimating unit cost database. This is especially important during times when labour and material pricing are volatile (Mochtar & Arditi, 2001: 410). Comparing data from the database can assist the estimator in ascertaining the current market conditions by comparing current situations with similar historical situations (Olhager & Selldin, 2007: 1475).
- Conceptual cost estimating and scheduling: As previously mentioned in this study, the database can also be used to create conceptual cost estimates. By mainly using the expensive mechanical equipment as a major cost directive, the database can be used through means of factors to determine the cost of the rest of the project.
- Strategic project planning: Using historical project information related to work breakdown structures, schedule logic and account coding, the lessons learned from successful and failed projects can be applied during the front-end planning session, start-up, etc. (Popescu & Jerz, 2008: CSC.03.2).

4.1 Development of an international cost database

A good estimator can readily estimate the cost of a domestic project using cost data that he is familiar with on a daily basis. Estimating international projects, however, involves working in foreign currencies (Kapp, 2004: 3), using different resource rates and working with labour crews operating at different levels of productivity (Koehn & Jagushte, 2005: INT.3.1).

One method of generating conceptual estimates on international work is to take the costs of a similar domestic project and convert those costs using published location factors. Reliable location factors for the type of project or the applicable country may not exist. These location factors also become unreliable when the scope of work or mix of work varies from the base project they are compared against (Aibino & Odeyinke, 2006: 667).

Hewitt (2007: INT.05.1) comments that the cornerstone of developing an international cost database is to start with a comprehensive detailed domestic work breakdown and resource database covering a similar scope of work as the project that is being estimated in the foreign country. The domestic WBS and resource database should include resource rates for labour, material and sub-contractors (Biffi, 2008: TCM.02.2). The data should also include typical crew makeup with associated production rates and productivity worker-hour factors. Construction equipment rates should be developed from first principles and include current equipment values, depreciation and interest rate formula, parts and labour repair factors, and equipment fuel consumption (Shapira & Goldenberg, 2007: 750). Refer to Chapter 2 for productivity factors.

4.1.1 Resource database conversion

Hewitt (2007: INT.05.1) demonstrates five basic steps towards converting a resource database into something that can be used to estimate project costs in a foreign country. These include the following:

- currency exchange conversion,
- labour rate conversion,
- equipment rate conversion,
- productivity rate conversion,
- material rate conversion.

Most estimating systems have functions that allow you to convert or factor resource rates as well as production rates. To better understand Hewitt's database converting steps it will be necessary to elaborate on these below.

4.1.2 Currency exchange conversion

The first step is to convert all resource rates according to the exchange rate between the domestic and foreign country. Galf and Monacelli (2008: 117) point out that this converts the database into the currency of the estimate. This would also handle the conversion of construction equipment and process equipment values that are normally procured competitively on an international basis. For example, the base value of any particular piece of equipment, excluding freight, taxes and duties, would be the same anywhere in the world.

4.1.3 Labour rate conversion

At this stage, the labour rates would be in the correct currency, but not necessarily in the local currency. Local currency refers to the rates that will apply to a certain area within the country in question. The conversion of rates is mainly done in two steps; first, by converting the labour rates and then, the management rates. The “trade rate factor” is the ratio of a sampling of the foreign trade rates to a sampling of the domestic database (Hale, 2008: 34). The management rates are converted in a similar fashion. It is necessary to do this in two steps because there is normally a much more significant variance between management and trade labour rates in developing countries than the more industrialised countries. Hewitt (2007: INT.05.2) points out that this variation may be as high as 20/1 in developing countries and 2/1 in more industrialised nations.

The rates can be converted globally first and updated in detail down to the resource level depending on the level of detail required. The lower the labour rates, the less important it is to update down the individual resource level. Depending on the precision required, labour rates may be factored based on payroll burden adjustments such as holiday pay, workers compensation, union dues, government deductions, as well as travel and subsistence requirements (Horman & Thomas, 2005: 840).

4.1.4 Construction equipment rate conversion

The conversion of equipment values and parts costs based on currency exchange rates has been discussed. The construction equipment rate conversion should now be taken further and adjusted according to the local mechanic rate, fuel price, power rate, interest rate and typical equipment use for the location of the project. For example, use factors for equipment are significantly different in northern countries where excavation

equipment may only be able to work eight to nine months a year (Shapira & Goldenberg, 2007: 752). The maintenance and repair component of the rates is significantly influenced by the mechanic's labour rate.

4.1.5 Productivity rate conversion

Productivity is usually measured in two ways, either as a production rate or a worker-hour factor (Song & AbouRizk, 2005: 362). For equipment dominated activities such as excavation or pipeline work, productivity is usually measured as a production rate per unit of time. Examples would be m^3/hour or meter/day.

The "production rate conversion factor" is based on equipment driven production rates to a sampling of the foreign production rates in the domestic database (Squires, Reid & Jeon, 2008: 85). There is usually not a significant difference in these rates using the same equipment. Although there may not be a significant difference in the production rate per unit of time, there is usually a significant difference in the worker-hours per unit of measure (Thomas *et al.,* 2003: 255). This is normally due to a difference in crew sizes due to union rules, safety considerations, work habits and cultural differences. Chapter 2 contains more information on productivity analysis.

Converting production rates is in itself a two step process. Firstly, the production rates should be factored and secondly, the crew sizes should be adjusted to even out crew mixes (O'Connor & Huh, 2005: 1015). As mentioned above, productivity can also be measured as a worker-hour factor. For a labour dominated item such as set and strip formwork or process piping, productivity is usually measured as a worker-hour factor, such as worker-hour/m^2.

The "labour worker-hour conversion factor" is based on labour driven production rates and is the ratio of a sampling of the foreign worker-hour factors to a sampling of worker-hour factors in the domestic database. Hewitt (2007: INT.05.3) indicates that there is usually a significant difference in these factors and that they can vary by as much as 200 percent.

4.1.6 Material rate conversion

The conversion of database rates to the currency in question has been discussed. A factoring of basic material commodity rates should now commence. The basic

commodity rates include cement, timber, steel, etc. (Hewitt, 2007: INT.05.3). This step requires the estimator to determine the local price for these commodities and then compare these with similar commodities in the domestic database. For example, the price of grout and concrete are mainly determined by the price of cement. By determining the ratio of cement prices one can factor all cement based material rates to a common base.

4.1.7 Updating the database to allow for international costing

A common approach when bidding for international projects is to convert a similar estimate prepared on a similar type project by using location factors (Oladapo *et al.,* 2008: 119). This is considered to be a top down conversion whereas the methodology discussed earlier in the chapter is a bottom-up conversion. The top down conversion relies on converting labour based worker-hour factors and tends to ignore equipment based production rates and crews. The top down conversion method will not work for equipment dominated projects or any project where productivity is equipment driven.

5.0 DATABASE FOR THE PETROCHEMICAL INDUSTRY

Ratio conceptual estimating has been in use for a number of years (Sonmez, 2004: 680). To simply refer a cost per pound produced is not good enough and that is why ratio conceptual estimating originated (Page, 1996: xv). Management of all organisations concerned demand more reasoning behind the structure of the estimate in question.

When a project is in its planning and evaluating stages, the cost of a complete design and definitive estimate would be, in most cases, too great to justify the design and estimate (Vilela & Longo, 2008: INT.11.1). Therefore, it becomes apparent that a less expensive method is needed to determine the feasibility of the plant in mind. A very important part of conceptual estimating is the development of a historical database (Assiskumar, 2008: EST.16.1).

The second part of this chapter is dedicated to the development of such a database, based on actual historical data of South African petrochemical projects. No specific information such as plant name and location have been mentioned due to confidentiality constraints, but all data collected have been obtained from typical petrochemical projects within the borders of South Africa. Addendum D reflects the

sets of data that were obtained from various projects. The data has been grouped together not by project, but rather by engineering field. The reason for this is that in South Africa it will be difficult to find enough petrochemical projects that are similar in operation, but when broken down can provide valuable information. A maximum of 45 different data fields might have been used in some cases, but this depends on the availability of the data.

In some cases, the material (equipment, etc.) was supplied by the client and the contractor only had to allow for installation of this equipment. In such cases, ratios were developed based on the installation quantities and rates only. In each such event it has been clearly stated that the specific portion of the database only includes for installation and not the supply of the equipment. This mostly occurred with the installation of mechanical equipment and piping.

The purpose of the database is to provide ratios for both quantities and rates of the most commonly used engineering fields that carry the most cost when constructing a petrochemical plant. The ratios are set out in such a way that it can be interactively applied if only limited information of a proposed new plant/addition to a plant is known. This is the essence of conceptual cost estimating as has been described in Chapter 3 and 4.

6.0 BASIC STRUCTURE OF DATABASE

The development of the data as contained within Addendum D was derived from several petrochemical projects that were constructed during recent history. Detail of the specific projects cannot be provided due to secrecy agreements, but the information required to build the data within the database was sufficient to draft adequate data.

An important consideration is that only final quantities (as built quantities) have been used. These quantities refer to the quantities as agreed between the contractor and the client at completion of the work. The rates used in the database are those that have been agreed between the contractor and the client. Considering the free market principle, one can then accept that the quantities and rates are market-related (Kuprenas & Nasr, 2007: 114). In other words, the ratios contained within Addendum D are based upon quantities and rates that would have been used by any competitive able contractor for that specific project at that point in time.

Data normalisation for the data contained in Addendum D for quantity based data was done in the sense that only data from ISBL (in-side battery limits) areas was used. If the data from OSBL (outside battery limits) areas were used, the ratios derived from this data would be skewed because the type of work between these areas normally differs quite a lot.

The rates to each of the 45 projects used to obtain data from have been kept the same (refer to Addendum D). Normalisation takes place in the form of “mean” and “median” adjustment which will be discussed in Chapter 8. Musgrove (2008: EST.07.3), however, points out that although data normalisation is important, it should be minimised. Once a certain project’s data requires too many adjustments it will also become suspect since it is very difficult to forecast some adjusting factors and in some cases these factors rely to a large extent on the estimator’s experience. Figure 5.3 illustrates how rates data can be normalised to suit the project’s needs.

The adjustment of rates as set out in Figure 5.3 is calculated by adjusting the percentages in columns A to F. The symbol “A”, for instance, represents “Escalation factor”, “B” represents “Size-of-the-project factor” and so forth. As the percentage allowance against each base rate gets adjusted, the rate contained in the “Total” column will alter. The effect of each percentage gets calculated on the original base rate. The total influence of all factors will in other words be calculated against the base rate and the net effect will be added to the original base rate.

The influence of each factor as stated in Figure 5.3 and the effect it has on the rate will be calculated according to the prevailing conditions (physical or economical) when the project in question was constructed. These adjustments can be made either by means of formulas applying published factors, as the case will be when adjusting escalation. In some cases there will be no published factors available and the estimator will have to rely on his judgment based on experience.

Civil rates data normalization										Date	Jan-10
Escalation factor	A										
Size-of-the-project factor	B

Figure 5.3: Civil rates data normalisation; base rates – 2003

The effects of escalation will be discussed in Chapter 6 of this study. The data as set out in Addendum D has been set up in such a way that escalation to the rates will not be necessary as it will not influence the ratios. The ratios derived from rate data only indicate the ratio between the rates. If a ratio conceptual estimate is being conducted, the principle rates, which will be the current market related rates, will be used together with the ratios to determine the new rate. Chapter 7 can be consulted for examples of how the ratio conceptual estimate will be executed.

The size of the project will influence the rates when considering economies of scale. It is common knowledge that the more one has to manufacture or construct of the same item, the less the unit cost becomes. Should a graph be drawn based on such data, the graph will not form a straight line, but a parabolic curve. Allowances for adjustments to

rates based on economies of scale can only be done based on experience and expert judgment, but the overall effect on the rates in general will not be that significant since mostly bigger sized project's (green field projects) date are being used to populate the database (Gerber, 2008: personal interview). In Figure 5.3 an allowance of 2% has been made to increase the rates slightly since the project from which the data was drawn was slightly smaller than the norm.

Market conditions also influence labour and material prices. The normal increase in rates is covered in the escalation allowance, but certain specific market or economic conditions may have influenced rates at the time that the project in question was constructed. The availability of labour, for instance, might have been very poor or it might have been difficult to obtain a certain material due to strikes or high demand elsewhere. The adjustment of market conditions is also based on experience and normally requires a collective effort from the project team. There were no special market conditions that required a change in the rates based on the data that was set out in Figure 5.3.

Oladapo *et al*., (2008: 118) comment on the development of location adjustment factors for the construction industry. In other parts of the world similar factors have been developed, but not much has been done in this regard in South Africa. Expert judgment will therefore be required to make the necessary alterations to the rates. This judgment will be driven by factors such as:

- added cost for transportation,
- availability of skilled labour,
- local labour union restrictions,
- local by-laws and regulations and standards,
- accessibility to other facilities,
- security concerns,
- safety and environmental considerations.

To determine the extent of the location factor the rates for projects in the same location of the proposed new project for which the estimate is being done need to be divided by the base rates of the project that is used as a base project. The calculation will be as follows:

Description	Unit	Rate X	Rate Y	% change
Site clearance	m²	R 5.00	R 5.50	10%
Demolish concrete	m³	R 1,200.00	R 1,320.00	10%
Bulk excavation	m³	R 70.00	R 77.00	10%
Excavation	m³	R 100.00	R 110.00	10%
Imported backfill and compact	m³	R 300.00	R 330.00	10%
High tensile rod reinforcement	t	R 8,650.00	R 9,515.00	10%
Concrete - supply and place	m³	R 1,150.00	R 1,265.00	10%
Pile augering	m	R 1,750.00	R 1,925.00	10%
80mm Concrete interlocking block paving	m²	R 200.00	R 220.00	10%
Brickwork	m²	R 550.00	R 605.00	10%

Rate X - Rate of project which is used as a basis for new rate
Rate Y - Rate of project in same location as estimated project

Table 5.3 Rate adjustment based on project location

The percentage calculated here correlates with the percentage used in Figure 5.3.

Complexity is difficult to measure and normally requires the project team to compare the complexity level of a specific project to that of the norm. The question might be raised as to what exactly is the “norm”? Over years of experience engineers acquire the ability to judge the level of complexity for each project. Because of the fact that only similar projects or engineering fields within projects are compared to each other, the necessity to adjust rates due to complexity are minimised.

Productivity differs according to the time in which it was measured as well as the location of the project (Enshassi, Mohamed, Mustafa & Mayer, 2007: 245). Different factors are published that can assist the estimator to adjust the productivity from one project to the next. In America, for example, the US Gulf Indexes are used (Thomas & Sakarcan, 1994: 230). In South Africa the available data is limited. Stats SA does, however, publish a productivity index (Stats SA, 2010: online available – 03 March 2010). Productivity, however, only applies to labour so the allocated percentage adjustment for productivity should only be applicable to the labour content of each rate. Figure 5.3 illustrates the data of a particular project. Although the productivity adjustment for the total trade will be the same, the allocation to each different item will vary depending on the labour content.

“Site clearance”, for example, has a 100% labour content. In this case the full productivity adjustment factor will apply. “Concrete – supply and place” on the other hand has a partial labour content of 35% (Williams, 1996: 118). The productivity index

will therefore only affect this portion of the rate. The adjustment of the data as contained in Figure 5.3 has been based on a base rate of 2003 and an adjustment to a target date of 2006.

Industry	**2003**	**2004**	**2005**	**2006**	**2007**
Printing and publishing	100.00	104.46	82.06	90.53	87.32
Industrial chemicals	100.00	77.62	70.94	67.12	55.40
Other chemicals	100.00	112.72	112.75	67.12	55.4
Petroleum and related products	100.00	104.49	90.04	85.82	114.17
Plastic products	100.00	103.74	89.82	104.30	131.66
Iron and steel	100.00	107.86	122.20	129.49	109.89
Non-ferrous metals	100.00	112.11	130.16	129.45	146.65
Non-electrical machinery	100.00	97.43	90.73	118.00	106.60
Electrical machinery	100.00	85.98	87.68	83.58	73.40
Transport equipment	100.00	95.76	85.50	79.48	80.84
Professional and scientific equipment	100.00	93.92	84.38	97.01	84.19
R&D intensive industries	100.00	99.65	95.12	100.95	106.07
Food products	100.00	90.38	109.31	125.00	150.78
Beverages	100.00	100.34	113.16	116.26	138.65
Tobacco	100.00	100.64	99.08	99.85	129.61
Textiles	100.00	87.89	117.75	89.06	128.92
Wearing apparel, except footwear	100.00	117.39	107.23	118.10	115.91
Leather and fur products	100.00	108.21	155.97	154.57	192.92
Footwear, except rubber or plastic	100.00	114.02	115.92	110.86	147.34
Wood products, except furniture	100.00	102.72	96.40	79.62	83.42
Furniture and fixtures, excluding metal	100.00	92.32	82.70	82.14	87.88
Paper and products	100.00	104.57	97.91	97.89	85.03
Rubber products	100.00	110.67	112.79	118.17	124.43
Non-metallic mineral products	100.00	87.89	89.87	97.78	79.99
Glass and products	100.00	121.02	149.95	116.42	128.10
Fabricated metal products	100.00	103.65	94.73	81.81	89.58
Other manufacturing industries	100.00	91.64	109.88	110.99	74.53

Table 5.2: Labour productivity index: 2003 – 2007 (2003 = 100)

Source: Stats SA, 2010: online available – 03 March 2010

Using the data as set out in Table 5.2 an adjustment of 11% (rounded off) has been made, based on the factor for “Other manufacturing industries”. Items with a lesser labour content attracted a lesser percentage increase.

The database has been developed in such a way as to represent the typical modern petrochemical plant that is currently being designed and built in South Africa. All the typical construction methods and typical plant and equipment used have been taken into account. The breakdown of the structure of the database is shown below. Drawings and photographs have been added to illustrate the typical design details of the structures at hand. The sources from which these drawings and photographs have been obtained can, however, not be revealed due to secrecy agreements.

A CIVIL WORKS

- A Site clearance and demolitions
- B Bulk earthworks
- C Piling
- D Road works
- E General paving and bunded areas
- F Manholes, valve boxes, catch basins and sumps
- G Pump and pipe support bases and plinths
- H Tank bases and bunding
- I Pipe and cable rack foundations
- J Simple structural foundations
- K Complex structural foundations
- L Concrete pipe racks and foundations
- M Concrete structure including concrete columns and beams
- N Major equipment bases with blast proof walls
- O Major equipment bases and elevated concrete structure
- P Buildings – concrete frame
- Q Buildings – steel
- R Canopies – steel
- S Weighbridge
- T Pump house
- U Cooling Tower
- V Emergency dam
- W Heavy duty cable tunnel

B STRUCTURAL STEEL

- A Basic platform
- B Pipe rack
- C Complex structure
- D Stack
- E Walkway
- F Cable gantry

C PIPING

- A ½ Inch
- B ¾ Inch
- C 1 Inch
- D 1 ½ Inch
- E 2 Inch
- F 3 Inch
- G 4 Inch
- H 6 Inch
- I 8 Inch
- J 10 Inch
- K 12 Inch
- L 14 Inch
- M 16 Inch
- N 18 Inch
- O 20 Inch
- P 36 Inch
- Q 42 Inch

D NDE TESTING

E MECHANICAL INSTALLATION

F PAINTING AND INSULATION

G ELECTRICAL AND INSTRUMENTATION

H PRELIMINARIES AND GENERAL

6.1 CIVIL WORKS (Item A in database – Addendum D)

6.1.1 Site clearance and demolitions (Item AA in database – Addendum D)

No specific allowance for site clearance and demolition works has been made in the database because in most cases these items differ from project to project. Demolition work is especially an item of variance from project to project and it will be dangerous to try and pin it down by means of ratio allocation. It will be best to make specific allowances for site clearance and demolitions when the estimate is being conducted.

6.1.2 Bulk earthworks (Item AB in database – Addendum D)

Bulk earthworks normally include soil replacement in areas with poor soil conditions and will in most cases be 2 to 4m deep depending on the structural requirements. The sides of the excavations are normally sloped and trimmed. In-situ beds needs to be ripped and compacted and the excavated soil will be carted away to a dump site.

6.1.3 Piling (Item AC in database – Addendum D)

The ratios for the allowance of piling include for the site establishment of the piling rig, setting-up of the rig at each piling position and drilling of the pile. The average pile diameter is 600mm. Piles will be on average 20m deep and of 35MPa concrete with a bulbous base. Pile rod reinforcement is included and each pile's integrity will be tested. A limited percentage of the piles will be load tested. Allowances can also be made for raking piles should the need arise.

6.1.4 Road works (Item AD in database – Addendum D)

Road works in petrochemical plants normally consist of bitumen surfaces with interlocking block paving or in-situ concrete at the intersections. Normal pre-cast kerbing is used and in most cases standard signage and road markings. The ratios allow for some basic sleeves, but the storm water drainage, manholes, etc. are provided for elsewhere.

6.1.5 General paving and bunded areas (Item AE in database – Addendum D)

When referred to in the process engineering context, paving refers to concrete paving to prevent soil contamination and to provide a safe and durable working platform. These areas will normally include the general areas under and around the structures and will in most cases cover the complete plant. Bunded areas refer to concrete finishing to areas that are enclosed with a concrete wall and a spill basin/catch pit. Bunding will occur when plants or portions of plants handle dangerous chemicals. The purpose of the bunding is to contain and collect any possible future spillage that might harm the environment.

6.1.6 Man holes, valve boxes, catch basins and sumps (Item AF in database – Addendum D)

All man holes, valve boxes, catch basins and sumps are covered by this section. Sundry items such as water stops are also included. Underground storm water pipe work is included here.

6.1.7 Pump and pipe support bases and plinths (Item AG in database – Addendum D)

These bases will only be the small bases and plinths that will support stands or some pieces of small equipment.

6.1.8 Tank bases and bunding (Item AH in database – Addendum D)

Almost every petrochemical project has some form of storage facilities and most of these come in the form of tanks. These tanks are (in most cases) constructed on site from metal sheeting on pre-constructed concrete bases. Depending on the tank capacity, there might be soil replacement and/or piling, but these items will be included in the relevant section. The bunding of the bases will also be included in these ratios. Figure 5.4 and Figure 5.5 show a plan and section of a tank base.

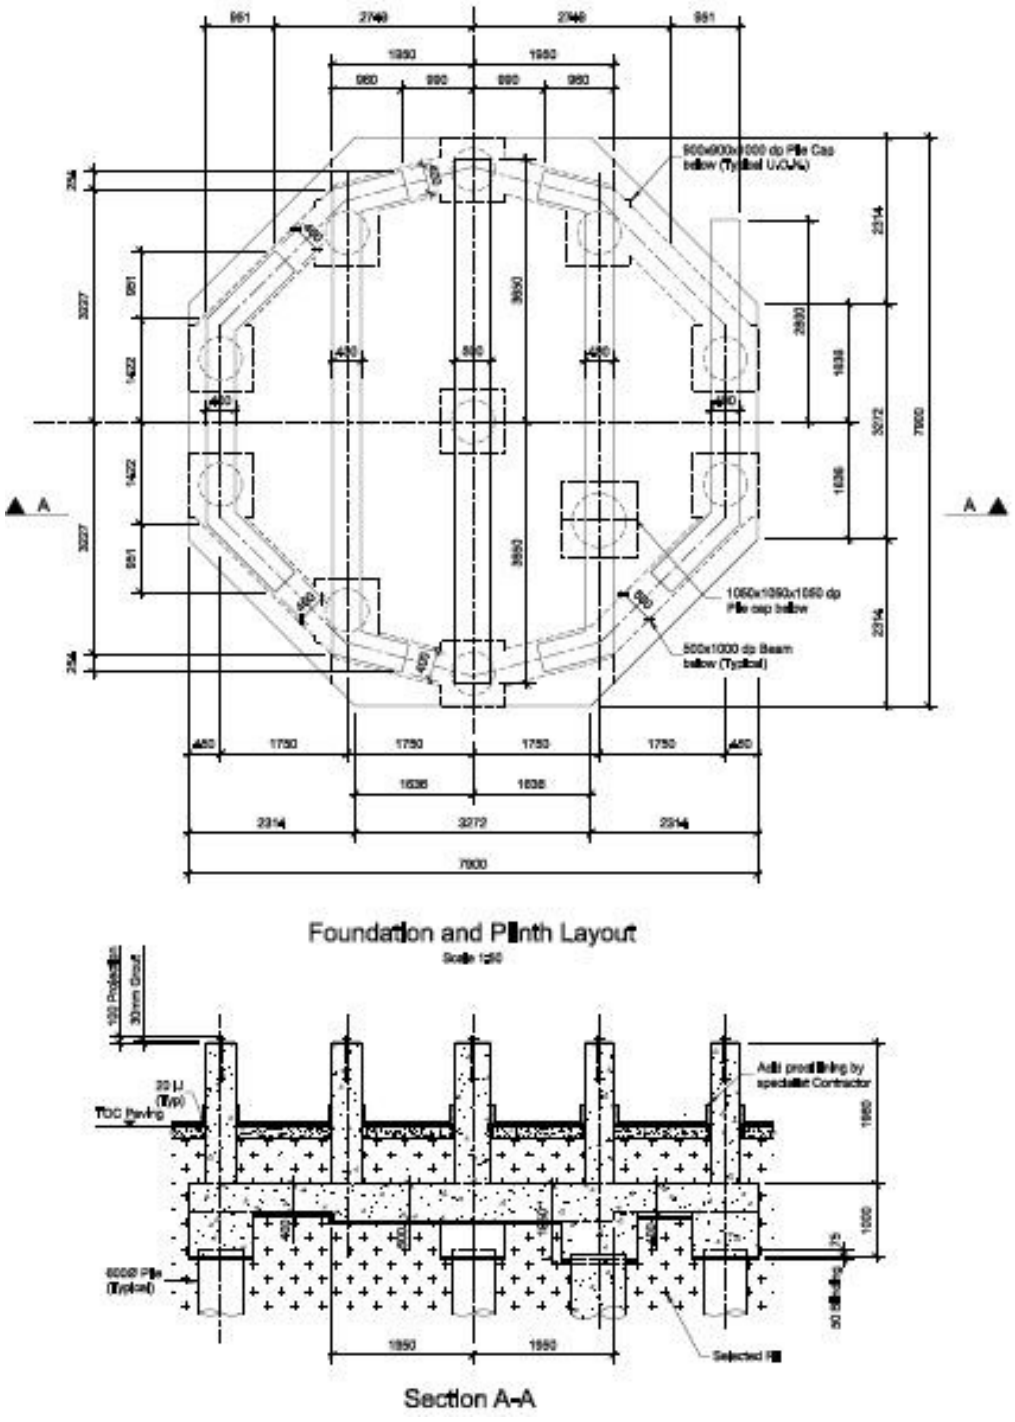

Figure 5.4: Large concrete tank base with cross walls to allow human access for inspection

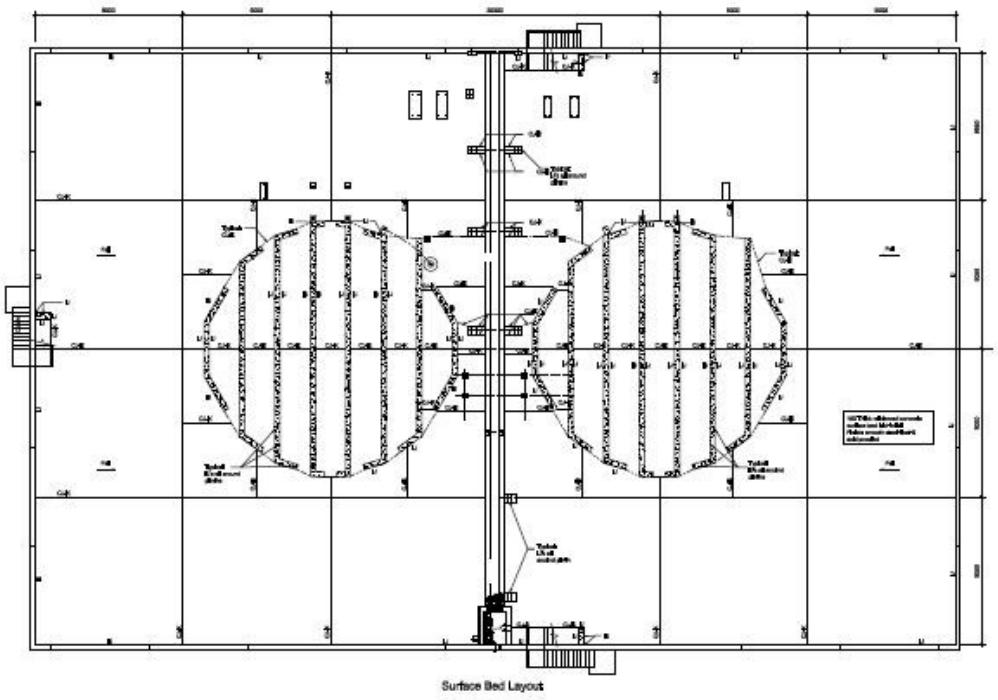

Figure 5.5: Plan of large tank bases with surrounding bunded area

6.1.9 Rack foundations (Item AI in database – Addendum D)

Figure 5.6 gives a plan of a typical lay-out of rack foundations which also forms the basis for the calculation of the ratios in Addendum D. In stable soil conditions, rack foundations will normally be simple foundations, but where ground conditions are suspect, piles are normally used.

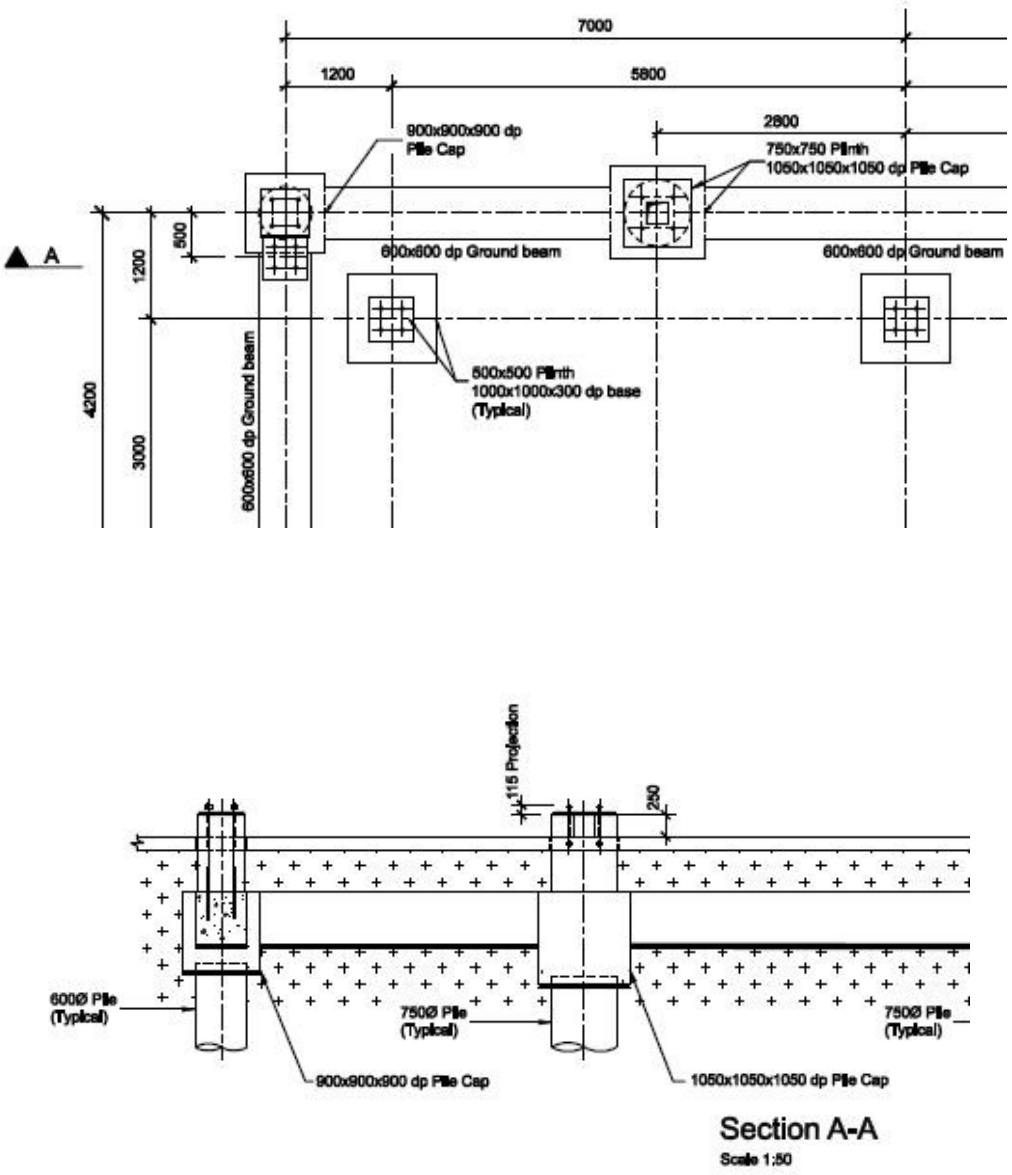

Figure 5.6: Typical pile cap and ground beam foundation

6.1.10 Simple structural foundations (Item AJ in database – Addendum D)

Figure 5.6 and Figure 5.7 show a typical pile cap/ground beam configuration.

6.1.11 Complex structural foundations (Item AK in database – Addendum D)

Photo 5.1 shows a complex concrete structure indicating cable racks and interconnecting structural steelwork. Photo 5.2 shows a close-up of complex concrete structures showing typical concrete beams and columns. Figure 5.6 depicts part of a plan of a typical foundation for a more complex structure.

Photo 5.1: Complex concrete structures indicating cable racks and interconnecting structural steelwork

Photo 5.2: Close-up of complex concrete structures showing typical concrete beams and columns.

6.1.12 Concrete pipe racks and foundations (Item AL in database – Addendum D)

Figure 5.7 illustrates the plan of a typical rack foundation. In most cases the racks will be structural steel with concrete foundations. Good soil conditions may not require piled foundations, depending on the structural loading of the foundations. Photo 5.1 and Photo 5.2 indicate the typical concrete super-structure where concrete columns and main beams are utilised. Addendum D contains the ratios of quantities and rates of concrete top structures with the foundations.

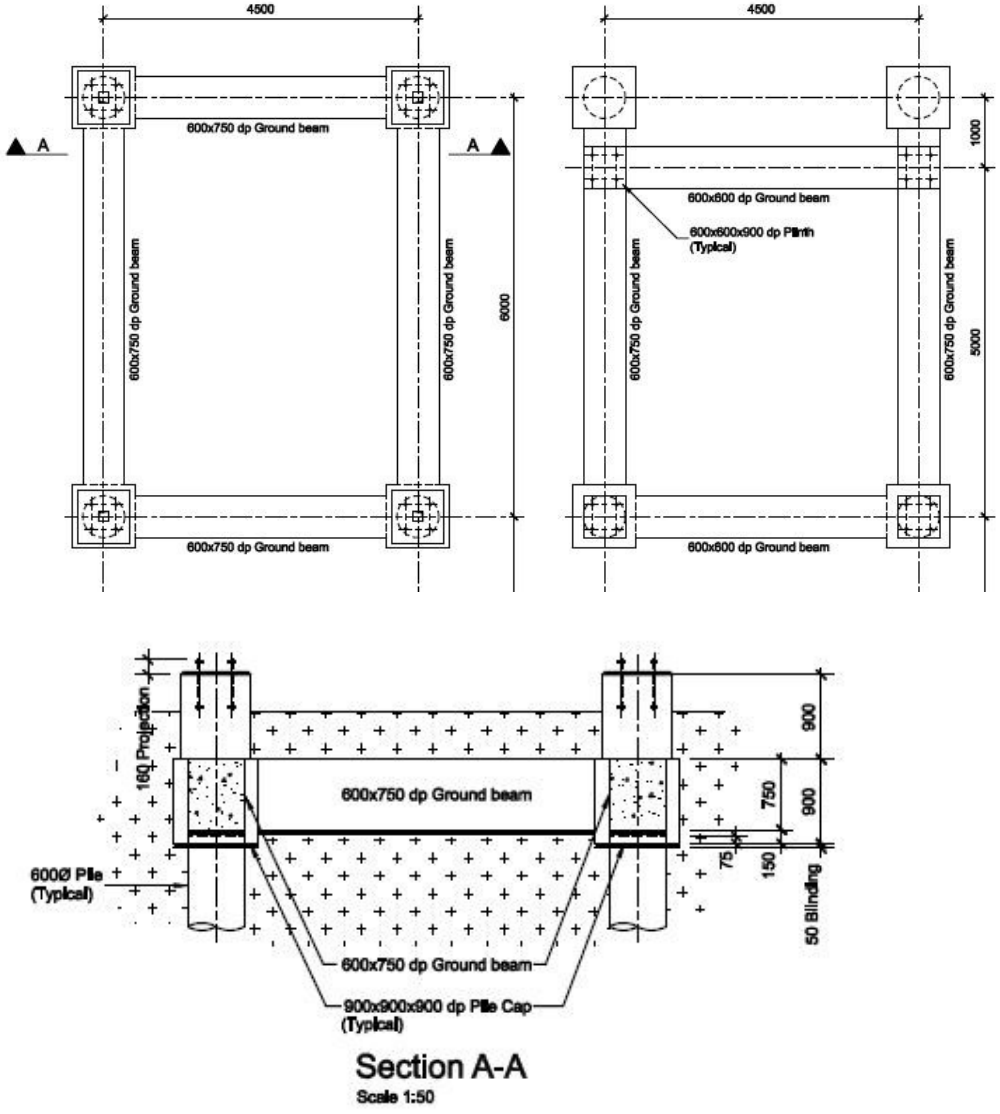

Figure 5.7: Plan of rack foundations indicating pile caps and ground beams

6.1.13 Concrete structure including concrete columns and beams (Item AM in database – Addendum D)

This type of structure is similar to concrete pipe structures (item AL in database), but it normally supports intricate equipment with high corrosion characteristics that will corrode steel structures. Photo 5.1 and Photo 5.2 demonstrate such structures. Structural steel members are connected to concrete members by means of cast-in steel plates welded to the steel members.

6.1.14 Major equipment bases with blast proof walls (Item AN in database – Addendum D)

Photo 5.3 shows a view of a large foundation type with blast proof walls. Blast proof walls are normally added to a structure if there is a possibility that the equipment will cause major damage to the surrounding structures if the blast (should it explode) is not at least partially contained.

Photo 5.3: Large foundation with blast proof walls

6.1.15 Major equipment bases including elevated structure (Item AO in database – Addendum D)

These types of bases will be used in conditions where heavy equipment must be placed and where aggressive chemicals are present.. Concrete beams and columns are used to prolong the corrosion on the material as shown in Photo 5.1, Photo 5.2 and Photo 5.4.

Photo 5.4: Typical large equipment base. Bolt pockets and bolts can be seen.

6.1.16 Buildings – concrete columns with brick in-fill (Item AP in database – Addendum D)

Most of the buildings constructed on petrochemical projects consist of a concrete frame with brick in-fill panels, steel roof construction and sheet metal roof covering. Photo 5.5 shows a typical sub-station building with transformer bays in the forefront. Figures 5.8, 5.9, 5.10, 5.11 and 5.12 illustrate typical sections, elevations and plans of such buildings.

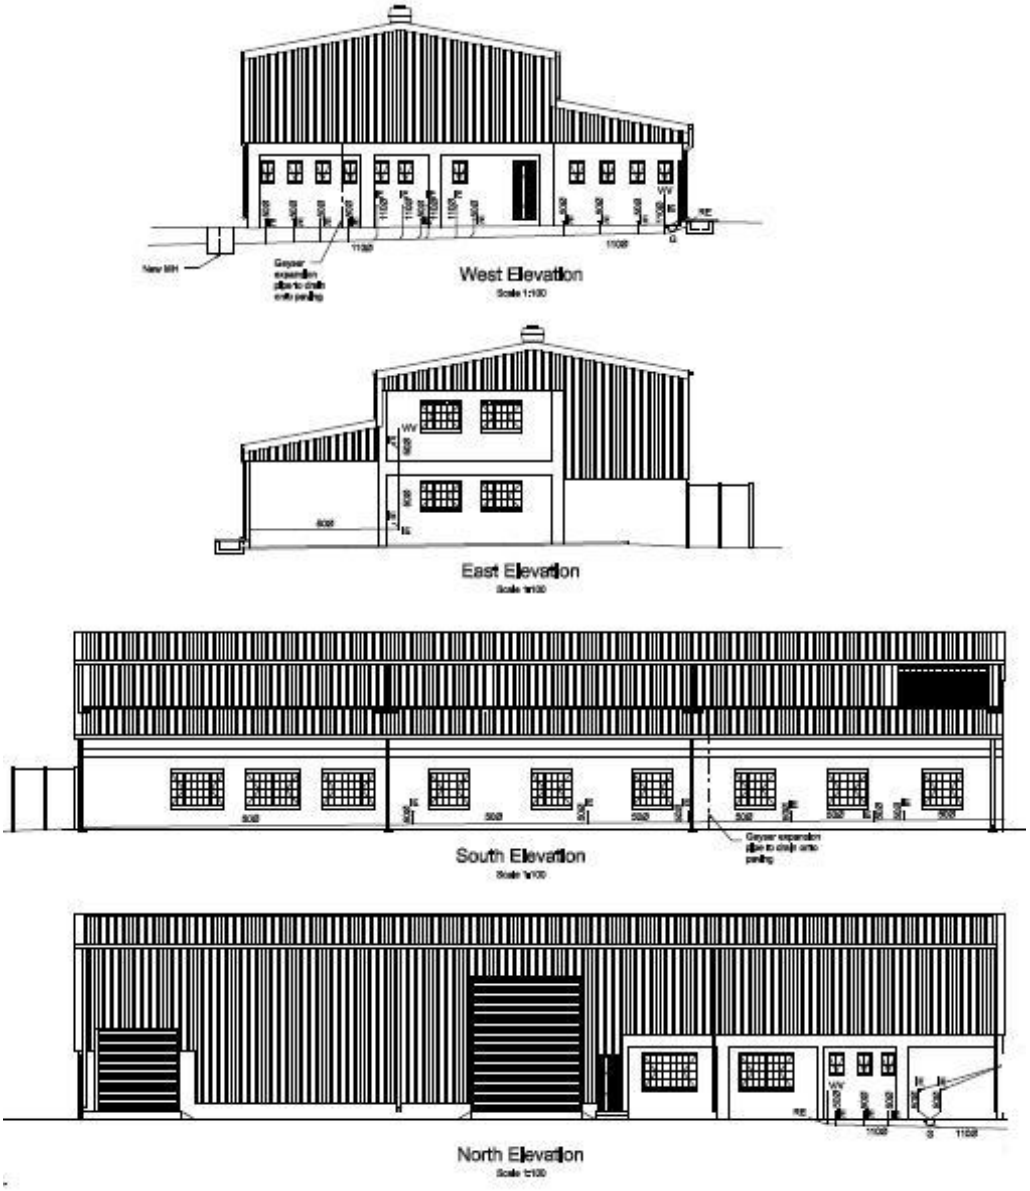

Figure 5.8: Elevations of a typical store/workshop building

6.1.17 Buildings – Structural steel frame with metal roof sheeting and side cladding (Item AQ in database – Addendum D)

Workshops and stores are generally constructed in this fashion. Figure 5.13 and 5.14 indicate a plan view and some elevations of the typical structures in question. The foundations of the structures are included in the ratios and form part of the total cost for the structures.

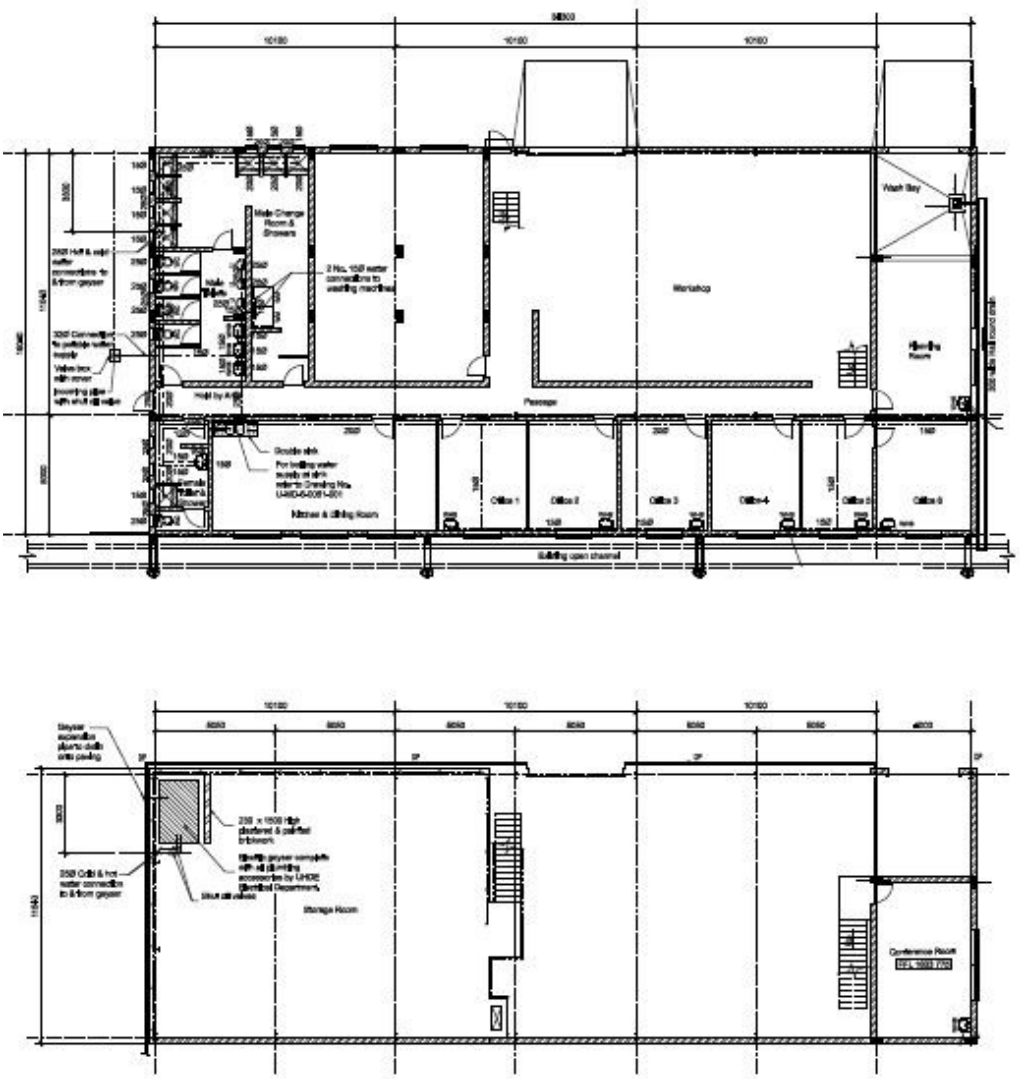

Figure 5.9: Plan and basic footprint of store/workshop building

Photo 5.5: Typical sub-station building

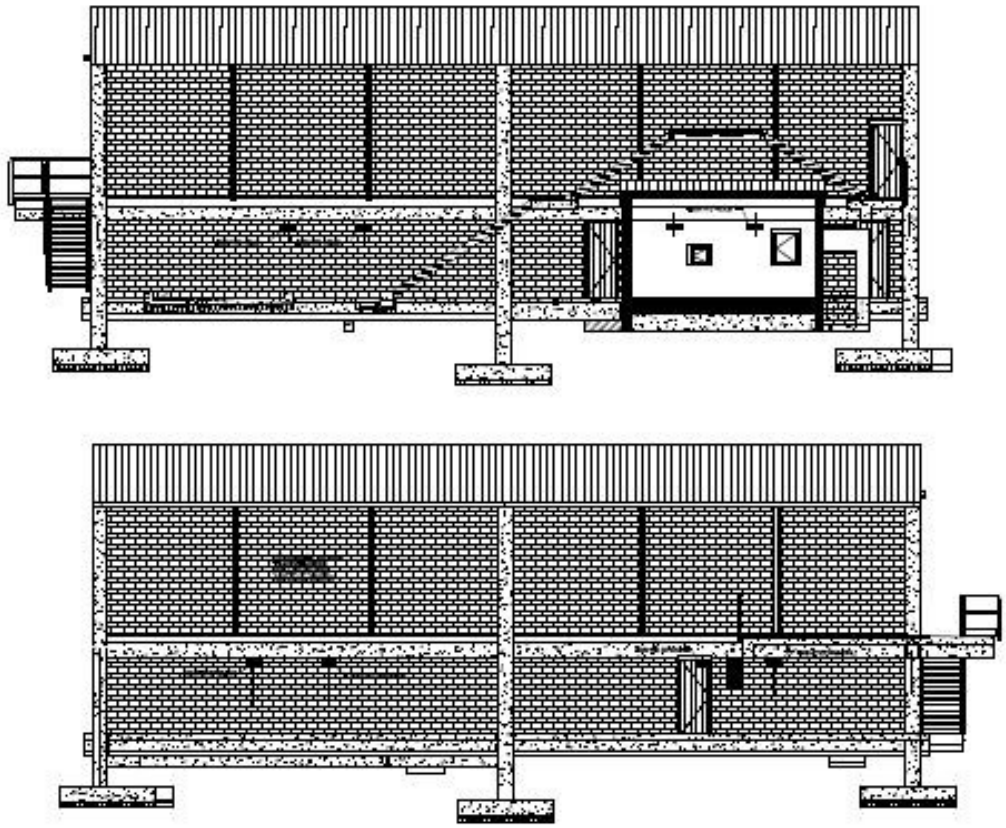

Figure 5.10: Typical elevations of concrete frame structure with brick in-fill panels

6.1.18 Steel canopy (Item AR in database – Addendum D)

Steel canopies are generally erected over equipment that must be protected from direct sunlight and rain. It consists of a steel structure with a roof and no side cladding. Figure 5.15 and 5.16 demonstrate a typical steel canopy structure. The ratios include civil works to allow for the complete cost associated with this type of structure.

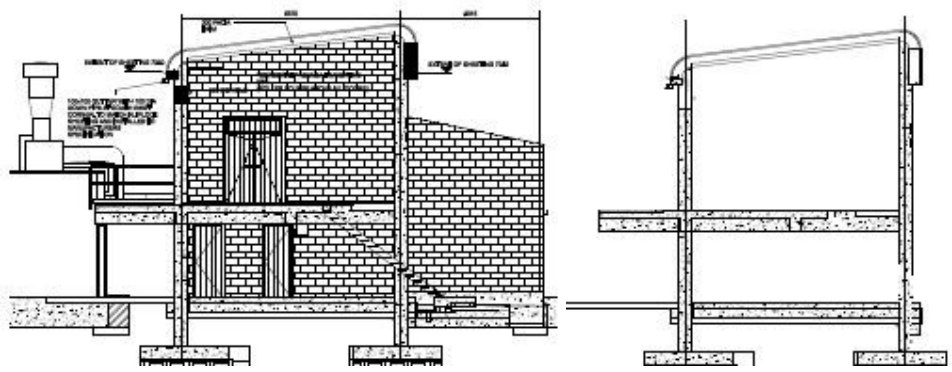

Figure 5.11: Sections through concrete frame with brick in-fill

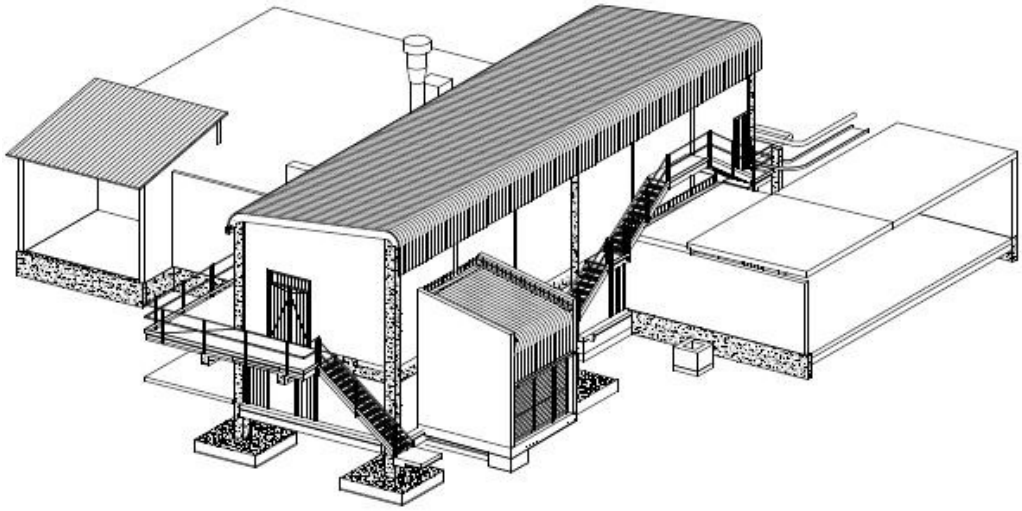

Figure 5.12: Three dimensional view of a typical brick building

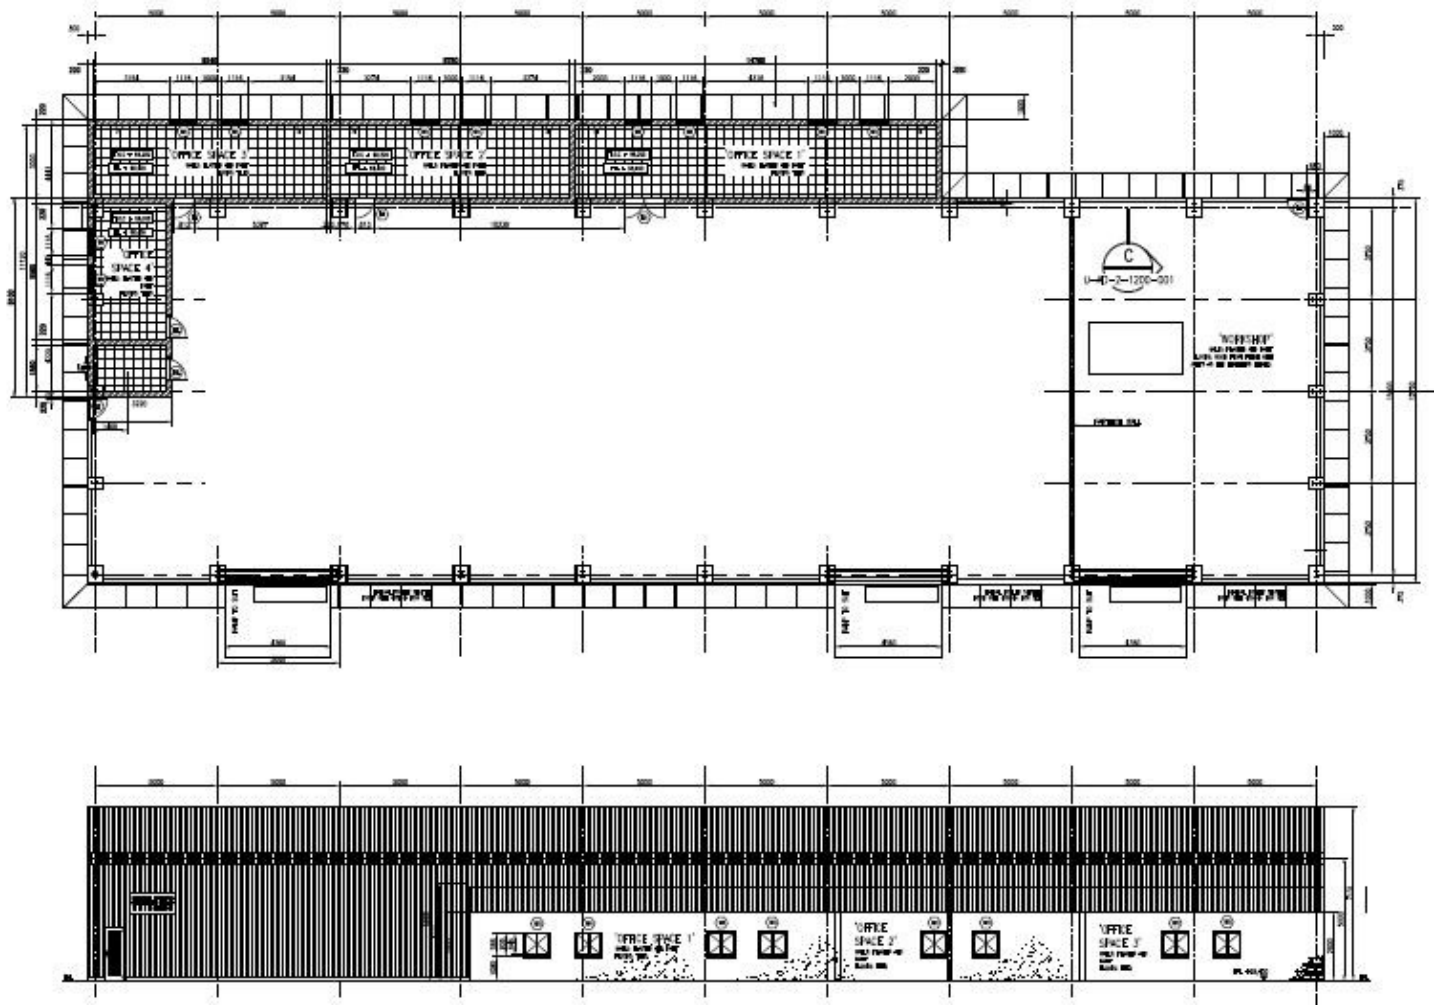

Figure 5.13: Plan and elevation of a structural steel frame building with metal roof and side sheeting and limited brickwork

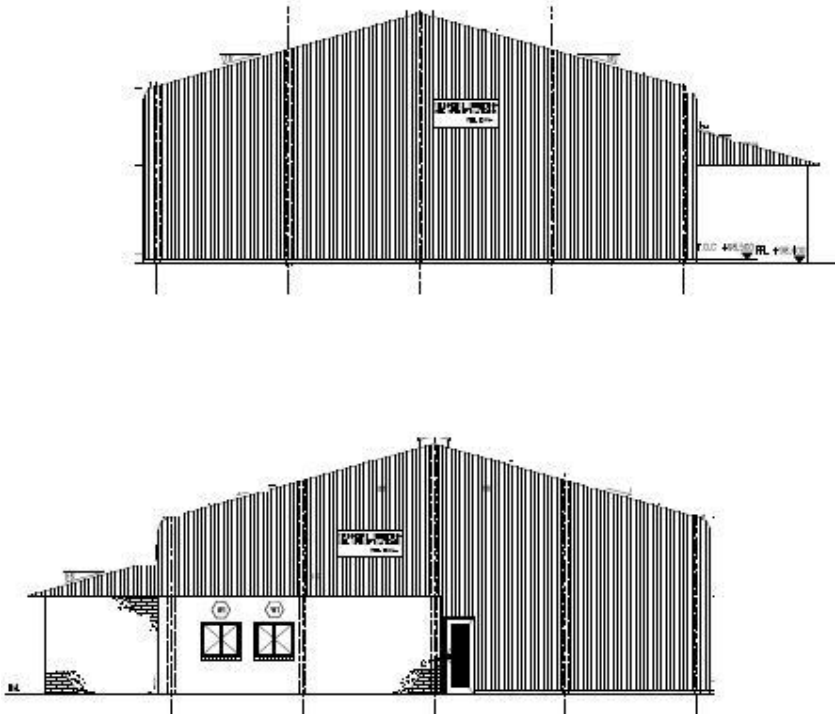

Figure 5.14: End elevations of structural steel building with steel roof and side cladding and some limited brick usage

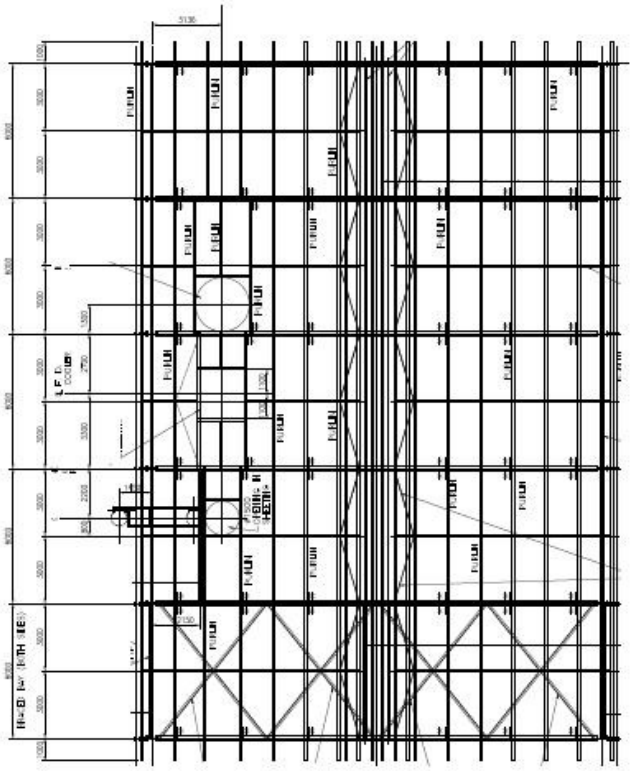

Figure 5.15: Plan view of steel canopy structure

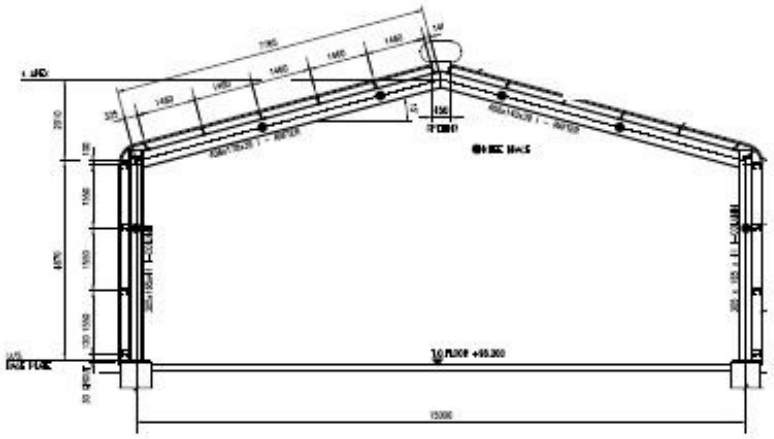

Figure 5.16: Section through steel canopy structure

6.1.19 Weighbridge (Item AS in database – Addendum D)

Figure 5.17 and 5.18 illustrate a typical weighbridge and office. The mechanical equipment (load cells, etc.) are housed in the concrete void and are not included in these calculations.

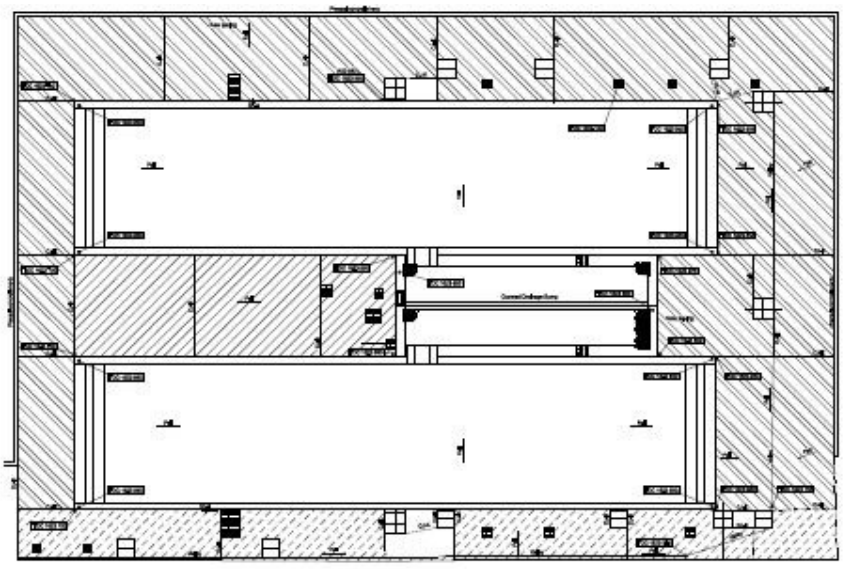

Figure 5.17: Typical weighbridge plan

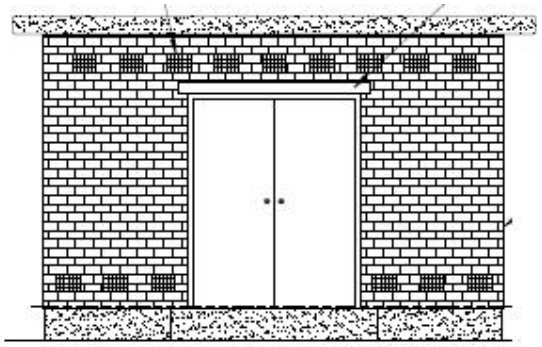

Figure 5.18: Typical weighbridge office

6.1.20 Pump house (Item AT in database – Addendum D)

Pump houses are generally constructed from a mixture of concrete and brickwork.

6.1.21 Cooling tower (Item AU in database – Addendum D)

Photo 5.6 illustrates a typical concrete cooling tower. Industrial cooling towers can be used to remove heat from various sources such as machinery or heated process material. The primary use of large, industrial cooling towers is to remove the heat absorbed in the circulating cooling water systems used in power plants, petroleum refineries, petrochemical plants, natural gas processing plants, food processing plants, semi-conductor plants, and other industrial facilities.

6.1.22 Emergency dam (Item AV in database – Addendum D)

The emergency dams in question are earth dams with liners and paving to prevent any seepage into the underground. These dams are normally empty and only act as spill-ways in case of emergency to prevent environmental damage.

Photo 5.6: The preferred water cooling tower design (vertical draft) in the petrochemical industry

6.1.23 Heavy duty cable tunnel (Item AW in database – Addendum D)

These cable tunnels are actually underground concrete service tunnels that house high voltage electrical cables. The ratios can be applied to any concrete service tunnel. Figure 5.19 indicates a longitudinal section and a cross section through such a tunnel.

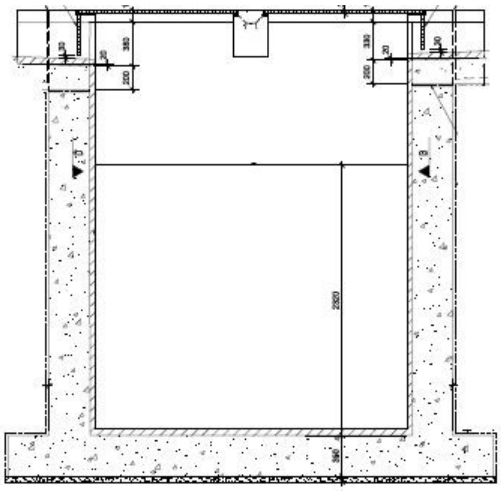

Figure 5.19: Cross section through typical cable tunnel

6.2 STRUCTURAL STEEL (Item B in database - Addendum D)

6.2.1 Basic platform (Item BA in database – Addendum D)

Figure 5.20 demonstrates the typical basic steel platform. These platforms normally consist of structural steel members (beams and columns) bolted onto concrete bases. The civil work is not included in the ratios. Steel grating provides a service platform and the hand railing is normally a purpose made steel railing.

6.2.2 Pipe rack (item BB in database – Addendum D)

Figure 5.21 shows some typical details of steel pipe racks. Pipe racks may have some limited access platforms and service platforms with cat ladders, but the bulk of the structure will consist of steel columns and beams.

6.2.3 Complex structure (Item BC in database – Addendum D)

Figures 5.22, 5.23 and 5.24 provide some images of how the typical complex steel supporting structure may look. Equipment can be accessed by means of steel stairs and cat ladders which spill out on grating.

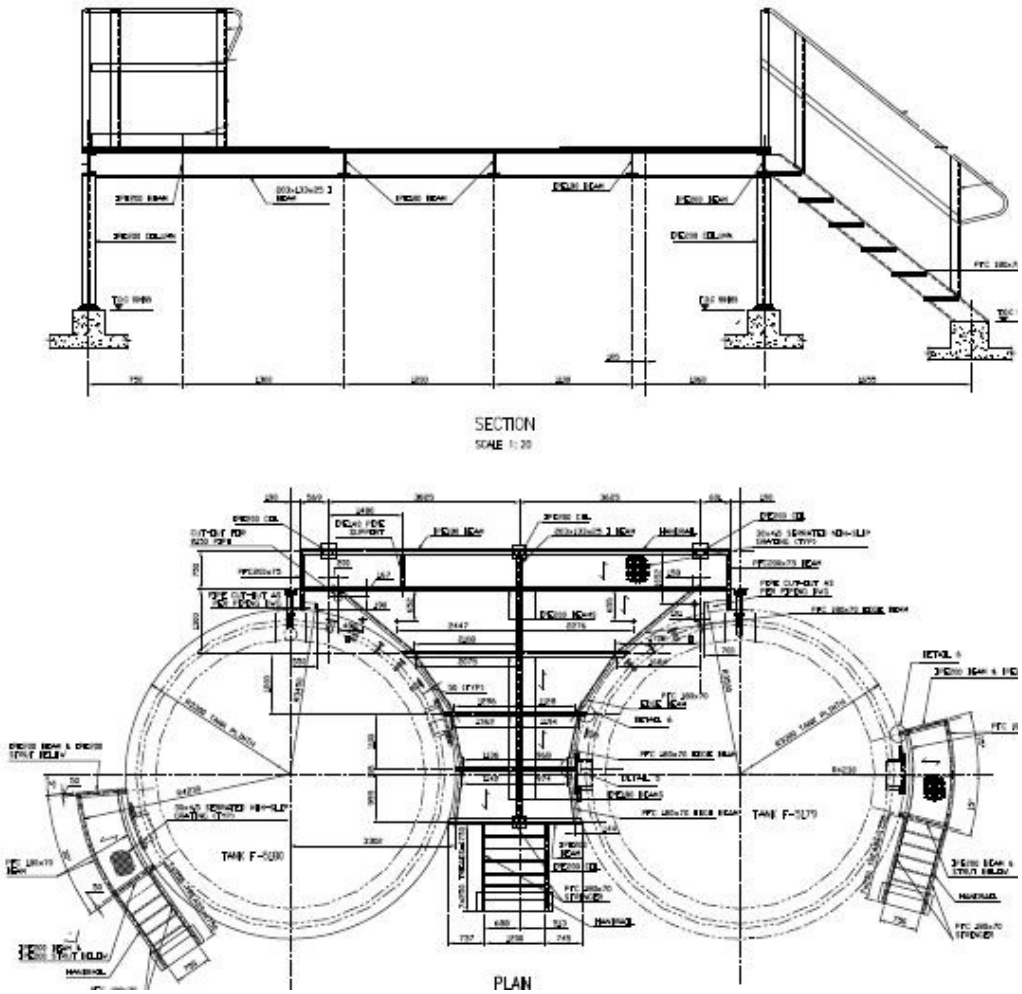

Figure 5.20: Basic steel platform

6.2.4 Stack (Item BD in database – Addendum D)

Figure 5.25 shows some typical elevations and sections of a steel supporting structure for a stack.

6.2.5 Walkway (Item BE in database – Addendum D)

Figure 5.26 demonstrates some details for a typical steel walkway.

6.2.6 Cable gantry (Item BF in database – Addendum D)

Elevations and sections of a typical steel cable gantry can be seen in Figure 5.27.

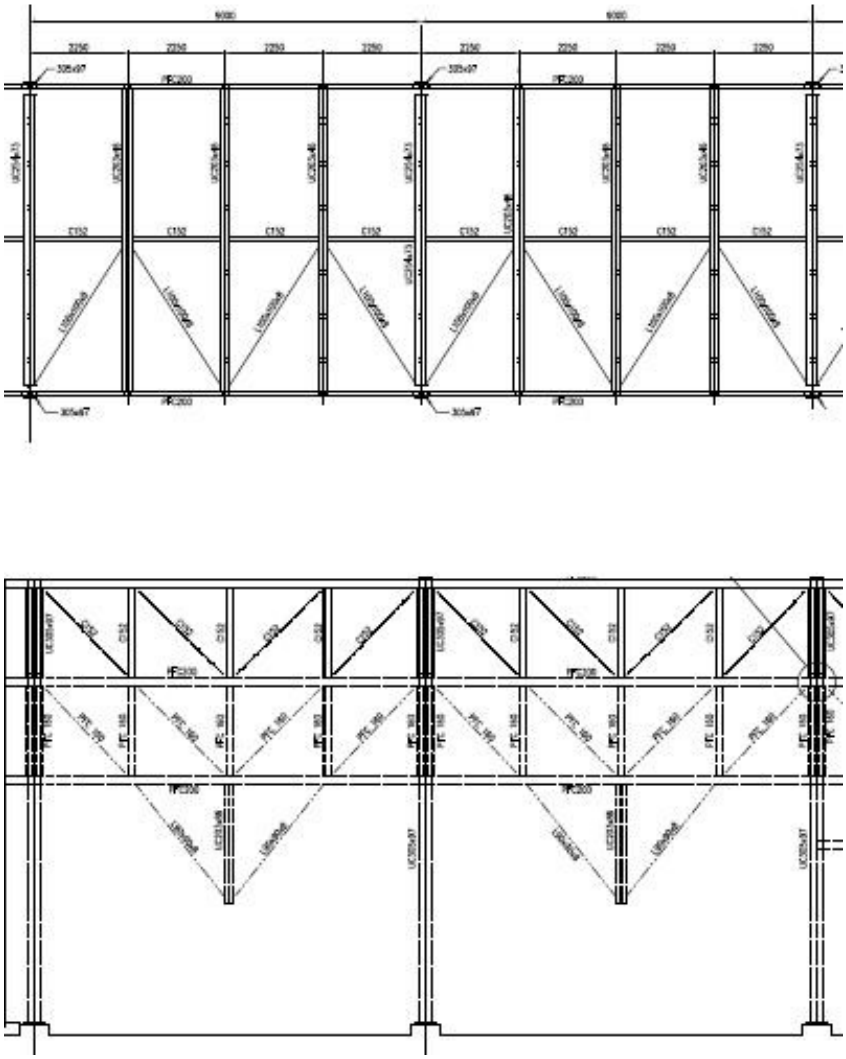

Figure 5.21: Plan of a typical steel pipe rack

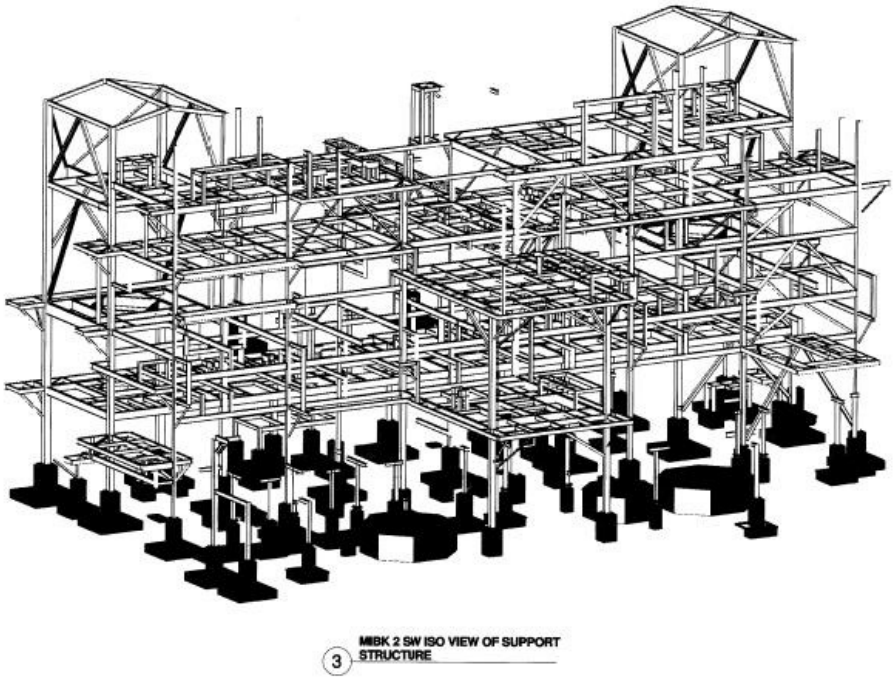

Figure 5.22: Three dimensional view of a typical complex steel supporting structure

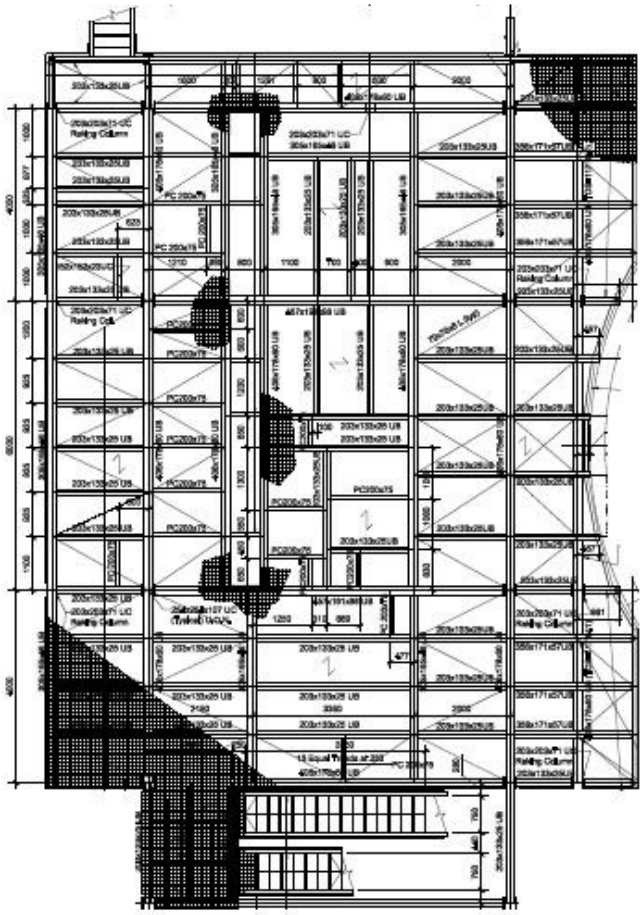

Figure 5.23: Plan of a typical complex steel supporting structure showing the stairwell

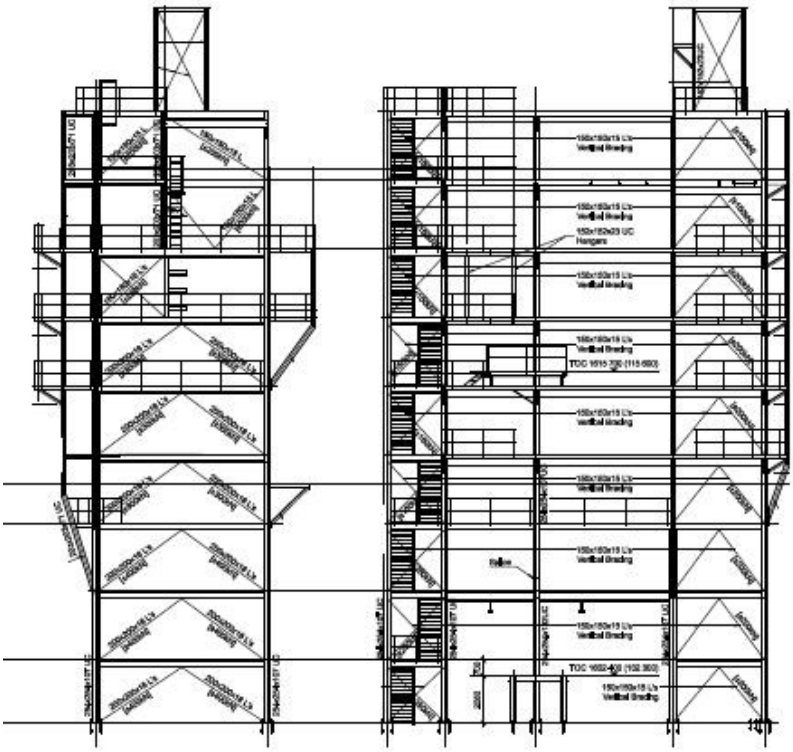

Figure 5.24: Section through typical complex steel supporting structure

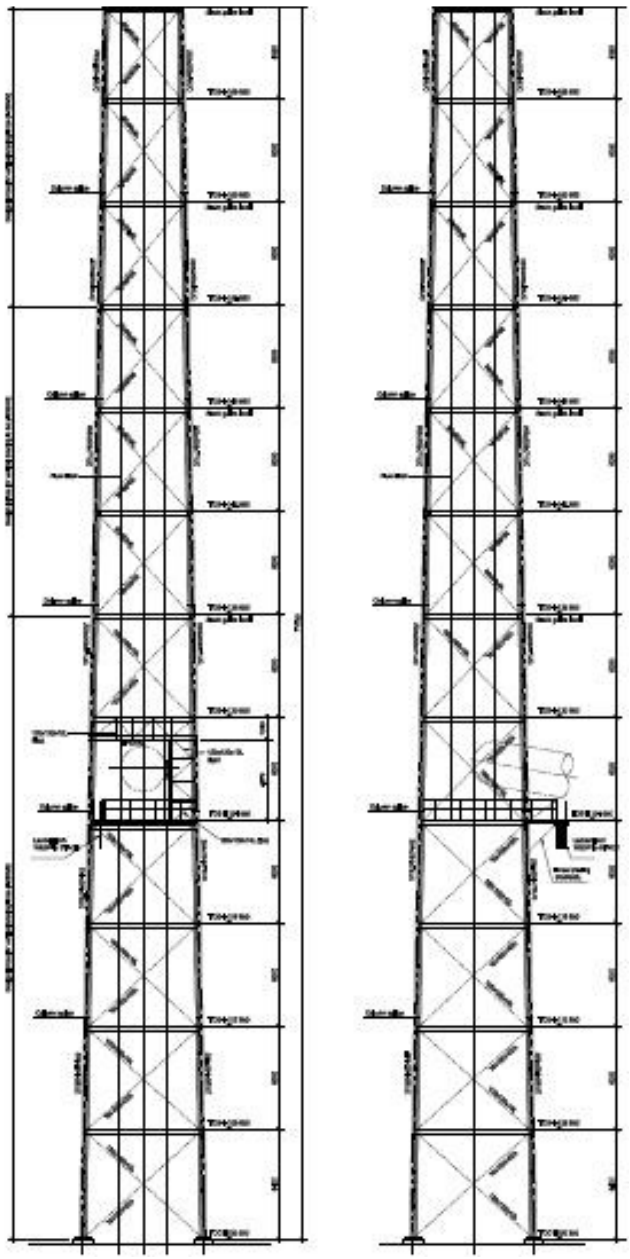

Figure 5.25: Longitudinal section through typical structural steelwork for stack

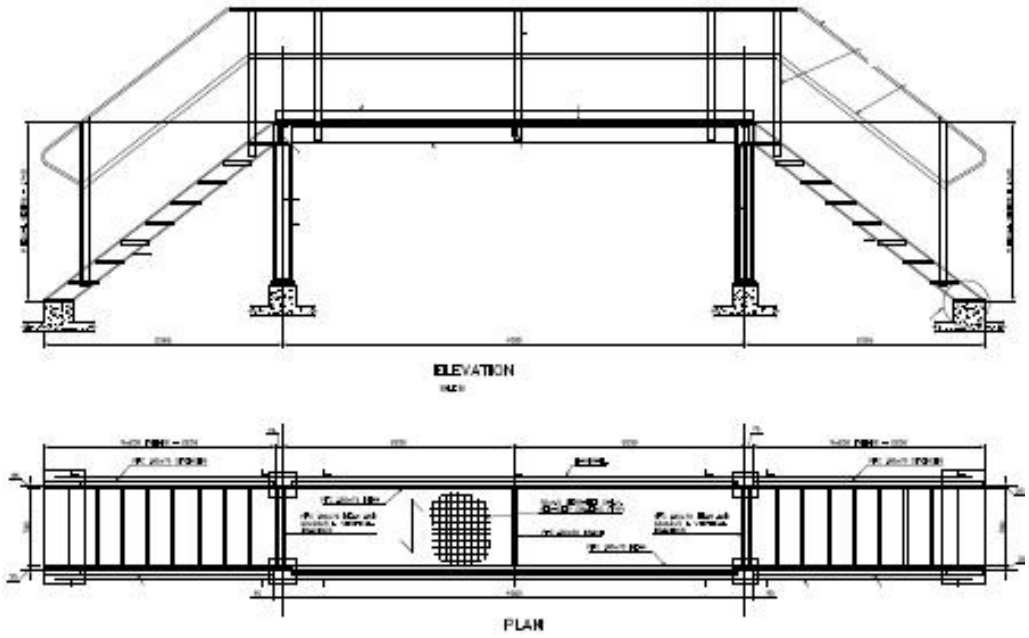

Figure 5.26: Elevation and plan for structural steel walkway

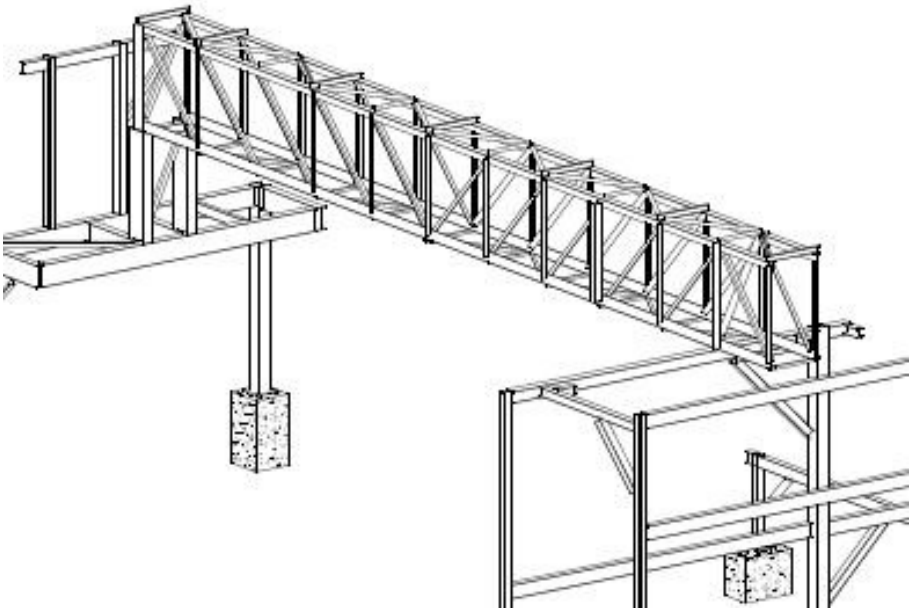

Figure 5.27: Three dimensional view of supporting steel for a cable rack

6.3 PIPING (Item C in database – Addendum D)

6.3.1 Piping – (sizes as per section CA to CQ contained in Addendum D)

Piping normally constitutes quite a sizable portion of the total cost involved in a process plant. The piping material is in most cases free issue material which will be procured by the client, but installed by the contractor. For this reason, the supply cost of the piping material has been ignored in this study, and only the installation of the piping material has been taken into consideration.

A popular method of measuring the labour content in the total piping installation is by making use of work units. One work unit includes all the direct labour (excluding supervision), small tools, scaffolding, cranage, etc. to complete, for example, 2,5 hours of work. Every item in the piping installation is then measured according to standard work unit allocations of which an example can be viewed in Addendum C. All pipe sizes and all work associated with the piping installation is covered by pre-determined company standards such as the ones illustrated in Addendum C.

6.4 NDE TESTING (Item D in database – Addendum D)

Non-destructive testing (NDT) is a wide group of analysis techniques used in science and industry to evaluate the properties of a material, component or system without causing damage. Because NDT does not permanently alter the article being inspected, it is a highly valuable technique that can save both money and time in product evaluation, troubleshooting, and research. Common methods used include radiographic testing (RT), dye penetration testing (DP), magnetic particle testing (MPT), post weld heat treatment and material hardness testing (MHT).

6.5 MECHANICAL INSTALLATION (Item E in database – Addendum D)

Mechanical equipment are almost always “free issued” to the contractor, meaning the client procure the equipment and will then officially hand it over to the contractor for safe keeping to be installed at a later stage. The installation will form part of the estimate and is normally measured in weight and priced per ton.

6.6 PAINTING AND INSULATION (Item F in database – Addendum D)

Painting and insulation (hot and cold) will be measured as the net area to be covered. It is normally measured in square meters except where the insulation of valves or other equipment on lines is necessary. The insulation of such items might be measured in number. Painting to structural steel is normally measured in tons.

6.7 ELECTRICAL AND INSTRUMENTATION (Item G in database – Addendum D)

Electrical wiring in general refers to insulated conductors used to carry electricity and associated devices. Electrical equipment includes any machine powered by electricity. They usually consist of an enclosure, a variety of electrical components, and often a power switch. The electrical scope normally includes all cabling, racking, equipment, etc. necessary to take the plant to production.

Instrumentation plays a significant role in both gathering information from the field and changing the field parameters, and as such is a key part of control loops. An instrument is a device that measures or manipulates variables such as flow, temperature, level, or pressure. Instruments include many varied contrivances which can be as simple as valves and transmitters, and as complex as analysers. Instruments often comprise of control systems for varied processes. The control of processes is one of the main branches of applied instrumentation.

Control instrumentation includes devices such as solenoids, valves, circuit breakers, and relays. These devices are able to change a field parameter and provide remote or automated control capabilities.

Transmitters are devices which produce an analog signal, usually in the form of a 4 to 20 mA electrical current signal, although many other options using voltage, frequency, or pressure are possible. This signal can be used to control other instruments directly, or it can be sent to a PLC, DCS, SCADA system, or other type of computerised controller, where it can be interpreted into readable values and used to control other devices and processes in the system.

6.8 PRELIMINARIES AND GENERAL (Item H in database – Addendum D)

All indirect costs associated with the construction of the plant will be allowed for in the Preliminaries and General. These include items such as management and supervision, on-site facilities, communication facilities, plant and equipment and ablution.

7.0 SUMMARY

The use of historical data to assist in making strategic decisions and to conduct cost estimating may play a significant role in improving competitiveness in the market. Before the data collection process can begin, certain methodologies and systems must be in place. Not only must company management support historical data collection, but they must also understand and actively promote this effort.

Conceptual estimating techniques are especially reliant on historical data. Good data normalisation and good sources of data will lead to better quality data. Improving the quality of the data will without doubt improve the quality of the estimate. Normalising the data, in other words adjusting the data to make it comparable to other sets of data, will include adjusting it for economic differences, site conditions, etc.

Data from in-house sources are preferable. Each organisation has its own methodology of construction with its own management styles. These aspects can influence the outcome of the data and eventually the outcome of the estimate. Given the global nature of chemical processes and clients/owners offering operating licenses to international companies, much of the data that is available is of an international nature. In cases like these, even further data normalisation is required. Currency exchange conversions, productivity rate conversions and international costing are but a few anomalies that need to be taken into account.

The typical database structure of a petrochemical plant has been depicted in this chapter. Brief descriptions of important notes have been entered to accompany Addendum D which contains the ratios of a typical process plant.

Construction risk has quite a significant influence on the price tendered and must be addressed. Depending on the nature of the project at hand, the project contingency can be a sizable amount. Arbitrary allowances of contingencies are dangerous and in the current competitive market cannot be allowed. Chapter 6 covers the theory behind

contingency analysis and the effect of and calculation of escalation which can have a serious effect on the total price, especially on projects with a long duration.

CHAPTER 6

COST ESCALATION AND CONTINGENCY ANALYSIS

1.0 INTRODUCTION

Cost escalation forecasting and contingency calculation and management are probably the most difficult concepts to quantify and to manage during the life of a construction project (Blyth & Kaka, 2006: 89). These two risks have a large probability of occurring, and they have an impact or consequence, making them typical construction risks. Mismanaging these risks can have a serious effect on the success of the project.

Prasad (2008: EST.S02.1) points out that risks will occur during the total life span of the project. When the probability and/or consequences related to these risks are reduced to the point that it is no longer a threat to the success of the project, the risk is eliminated (Koller, 2005: 4). It is therefore important to note what the effect or consequences of risk will be. This process is known as assessment and has to take into consideration the complete process of risk identification, risk analyses and risk evaluation (Garlick, 2007: 3).

A handy method to achieve a range of solutions when conducting risk analysis is the Monte Carlo analysis process (Vargas, 2004: CSC.16.2). This technique is generally used to solve problems for which the definition of specific solution equations to calculate a specific answer is either too complex or too cumbersome to be practical. In a sense a Monte Carlo analysis is a form of a repeatable experiment whose accuracy can be increased should the number of tests be increased (Patterson, 2006: IT.05.03). Monte Carlo analysis is, however, not a substitute for good quality historical data and the use of historical data should always be promoted (Whiteside, 2008: EST.04.2).

Construction escalation is an effect of inflation. The general increase of prices does not necessarily constitute inflation (Ball & Petrowski, 2007: EST.09.1). The costs of commodities should rise fairly rapidly to be classified as inflation. The definition of inflation should therefore be that the rise of prices occurs over a relative short period of time. Two main types of inflation are identified, cost-push and demand-pull; the latter almost always having more extreme effects than the first (Flemming & Koppelman, 2009: 22).

The effect of inflation is not distributed evenly, and as a consequence there are hidden costs and benefits to others from this decrease in purchasing power. Lum (2004: 32) states that with high inflation, purchasing power is redistributed from those on fixed incomes, such as pensioners, towards those with variable incomes. The redistribution of purchasing power will also occur between international trading partners. The best counter measures to restore a sound growth rate in the economy are to increase the amount of resources available and the efficiency of their use (Gransberg & Carlisle, 2008: EST.09.1).

Inflation is considered to be a general change in prices caused by the debasement of the value of the currency (Lum, 2004: 32). Construction cost escalation includes the effect of inflation, but reflects changes in price drivers such as productivity and technology, as well as changes in market conditions such as high demand, labour shortages and profit margins. Construction escalation varies for different capital components such as office and field labour, bulk material and equipment. It also varies by region and procurement strategy (Olhager & Selldin, 2007: 1470).

Hassanein and Khalil (2008: 20) indicate that forecasting escalation rates can play an important role in project profitability or viability especially for large multi-year construction and development projects. The estimator must predict the cost for goods and services that must be procured in the future, perhaps many years from now (Hollmann & Dysert, 2007: EST.01.4). Some of the more important factors influencing cost escalation can be described as follows: major natural disasters, increase in material cost, bid market disruptions, high volume of construction work, and the regulatory climate.

Measuring and tracking cost escalation requires a reasonably accurate index based on information that is reliable and captures a wide enough spectrum of data that all aspects of escalation are covered (Touran & Lopez, 2006: 855). Engineering construction indices such as SEIFSA and PPI are two examples of escalation indices that are used in South Africa to calculate the effect of escalation on construction costs. Each index should be evaluated on how it is intended to be used for a particular project or process calculation. Indices which are based on statistical information are more likely to be objective than those based on the opinions or views of individuals.

Cost indices should, however, be used with caution since these indices are only approximations intended to represent the average trend for a large group of projects in

a broad region (Butts, 2007: EST.08.1). The indices are generic and conceptual in nature, and judgment must be applied in using them in any given situation. The dominant escalator in the current market is poor allocation of risk. To manage cost escalation and minimise the impact of future cost increases or other factors which will arise to put additional pressure on the market, project owners need to change how they think about, and handle projects.

Escalation is not controlled and driven by the management of a company. It is macro-economics driven and largely beyond the control of the estimator (Gransberg & Carlisles, 2008: EST.09.1). Even the best defined and managed projects will face price increases driven by underlying economic conditions. Escalation has, however, become a "politically correct" hiding place for contingency as many estimators find it difficult to provide proper reasoning as to why they made certain contingency allowances. The "un-scientific" nature of escalation forecasting makes it a vulnerable entry within the estimate.

Contingency is, however, not an allowance for escalation, but is intended to mitigate the adverse impacts of unforeseen events (Whiteside, 2007: EST.04.1). It is a reserve against risk or estimate assumptions and a function of design, definition, estimating method, estimator's experience, time frame, schedule probability, new technology, remoteness of job site, engineering progress at the time of estimate and material commitment at the time of the estimate.

Typical contributors to cost overruns on projects in the oil and gas industry can be summarised as:

- change orders,
- level of scope definition,
- bid process,
- contract risk,
- market conditions,
- risk management issues, and
- performance.

Contingency funds are widely accepted budgeting tools for affording projects acceptable levels of cost reliability (Blyth & Kaka, 2006: 87). However, a global

contingency pool can be misleading early in the project. Risk associated with initial project definition can consume a disproportionate amount of contingency, exhausting the available reserve funding prior to project completion.

The majority of projects set their contingency using techniques that can be grouped into one of three categories: predetermined percentage, expert's judgment, and risk analysis. Irrespective of the method used to determine contingency, it should be managed (Prasad, 2008: EST.S02.1). Contingency funds are included in development budgets to provide managers with the flexibility required to address uncertainties and deviations that threaten achieving the objectives. Improving contingency management requires an understanding of how managers make budget contingency decisions and the impacts of those decisions on performance (Ripley, 2004: CSC.08.1).

2.0 RISK MANAGEMENT

Garlick (2007: 3) points out that managers in all organisations have to make decisions and act bearing future uncertainty in mind. Koller (2005: 4) took the loose connotation of risk and uncertainty and broke it down into four categories: risk, uncertainty, probability, and consequence. To him, there seems to be a propensity to confuse probability and/or uncertainty with risk. These four entities are, however, distinct and should not be confused. Garlick (2007: 3) and Khan (2007: 14) mention that risk management is the knowledge that the future cannot be predicted with certainty, but steps can be taken that will favour preferable outcomes over less attractive ones.

Garlick (2007: 3) defines risk management as:

> *"Risk management is the discipline for making decisions and acting whilst demonstrably taking account of this potential for different future outcomes."*

A manager applying risk management should be able to understand risk in all its forms. Koller (2005: 4) describes risk as follows:

> *"A pertinent event for which there is a textual description."*

Risk is typically associated with at least two parameters:

- Probability of occurrence
- Consequence (impact) of occurrence

About each of these attributes, one could be sure. For example, if one were to flip a coin, one can be sure that the probability of the coin landing “heads-up” is 50%. You might also be sure about the prize of winning. In such a case there is no uncertainty about the probability or consequence. However, in most business situations one cannot state with 100% certainty just what the probability will be, nor what the consequence will be if the risk is realised. This creates uncertainty (Koller, 2005: 5).

Uncertainty can at least be related to probability and impact of risk (Lee & Halpin, 2003: 432). Uncertainty is typically, but not always, represented by a range of values that encompasses the range of possibilities. Uncertainties related to construction may include the following:

- Uncertainty regarding the probability of an abnormal amount of foul weather.
- Uncertainty about the probability of a union strike during the cause of the project.
- Uncertainty regarding the possibility that permit delays might be experienced.

Koller (2005: 6) mentions that the cost of these uncertainties can be calculated by the percentage change between what is considered to be normal and what is conceived to be abnormal, multiplied by the number of days and the cost per day. When all risks and uncertainties have been identified, steps can be taken to mitigate these risks and uncertainties (Odeyinka, Lowe & Kaka, 2008: 10). Whenever uncertainty is involved, a Monte Carlo analysis is normally used that allows combinations of distributions. More will follow in this study on Monte Carlo analysis.

Picken and Mak (2001: 318) indicate that there are different types of risk at different stages in the project life cycle. From the tendering stage (Wong & Hui, 2006: 426) until late in the project life cycle, risks will be experienced. At the feasibility and inception stages, for example, the client may not have decided exactly on the floor area that is required, or the amount of additional floor area over what the basic may be in abeyance. Such matters will create uncertainty from an estimator’s point of view. The depth of piling for foundations is another typical example of uncertainty. Some of the

uncertainties will be eliminated or clarified as the planning of the project develops towards the detailed design stage.

When the probability and/or consequence related to risk is reduced to the point that it is no longer considered to be a threat to success, the risk is eliminated. Koller (2005: 6) states that one should not strive to minimise risk, but rather to eliminate risk. The reduction in probability and consequence should, however, be an aim for management to strive towards (Jha & Devaya, 2008: 340).

When estimating risk it is important to understand what risk entails and what the consequences of risk might be. Garlick (2007: 6) describes the three major business risks as follows:

- Systematic under-estimation of the cost and time to carry out activities.
- Systematic under-estimation of the management resources and managerial talent needed to achieve objectives successfully.
- The essential unpredictability of the future environment.

Arrow (2008: RISK.01.1) demonstrates in Table 6.1 the “hard” and “soft” benefits of risk management.

“Hard benefits”		“Soft benefits”	
1	Enables better planning, scheduling and budgeting.	1	Improves corporate experience and general communication.
2	Increases the likelihood of a project adhering to its schedules and budgets.	2	Leads to common understanding and improved team spirit.
3	Leads to the use of the most suitable type of contract.	3	Helps distinguish between good and bad management.
4	Allows a more meaningful assessment of contingency fund.	4	Helps develop the ability of staff to assess risks.
5	Discourages the acceptance of financially unsound projects.	5	Focuses project management attention on the real and most important risks.

"Hard benefits"		"Soft benefits"	
6	Contributes to the build-up of statistical information for better decision making.	6	Facilitates greater risk-taking, thus increasing benefits gained.
7	Enables a more objective comparison of alternatives.	7	Demonstrates a responsible approach to clients.
8	Identifies and allocates responsibility to the best Risk Owner.	8	Provides a fresh view of the personnel issues on a project.

2.1 The risk management process

Figure 6.1 emphasises the broad scope of risk management compared with just risk assessment. In particular, it emphasises the importance of implementation. Risk management is an active (or pro-active) continuous activity (Garlick, 2007: 16).

Garlick (2007: 14) defines risk management as follows:

> *"Risk management is the culture, process and structures that are directed towards realizing potential opportunities whilst managing adverse effects."*

2.2 Risk assessment

Garlick (2007: 13) defines risk assessment as follows:

> *"Risk assessment is the overall process of risk identification, risk analysis and risk evaluation."*

Starting the risk analysis process will be the identification of the risks involved. Risk analysis is dependent on what risks have been identified. The standard method is generally to engage in some sort of brainstorming session with the intention of

promoting comprehensiveness by systematically considering what can go wrong with each element of a project or system. People from different functions should sit together and understand the activity and share their perspectives on the risks and opportunities involved in their projects and what should be done about them (Kubitscheck, 2000: 39).

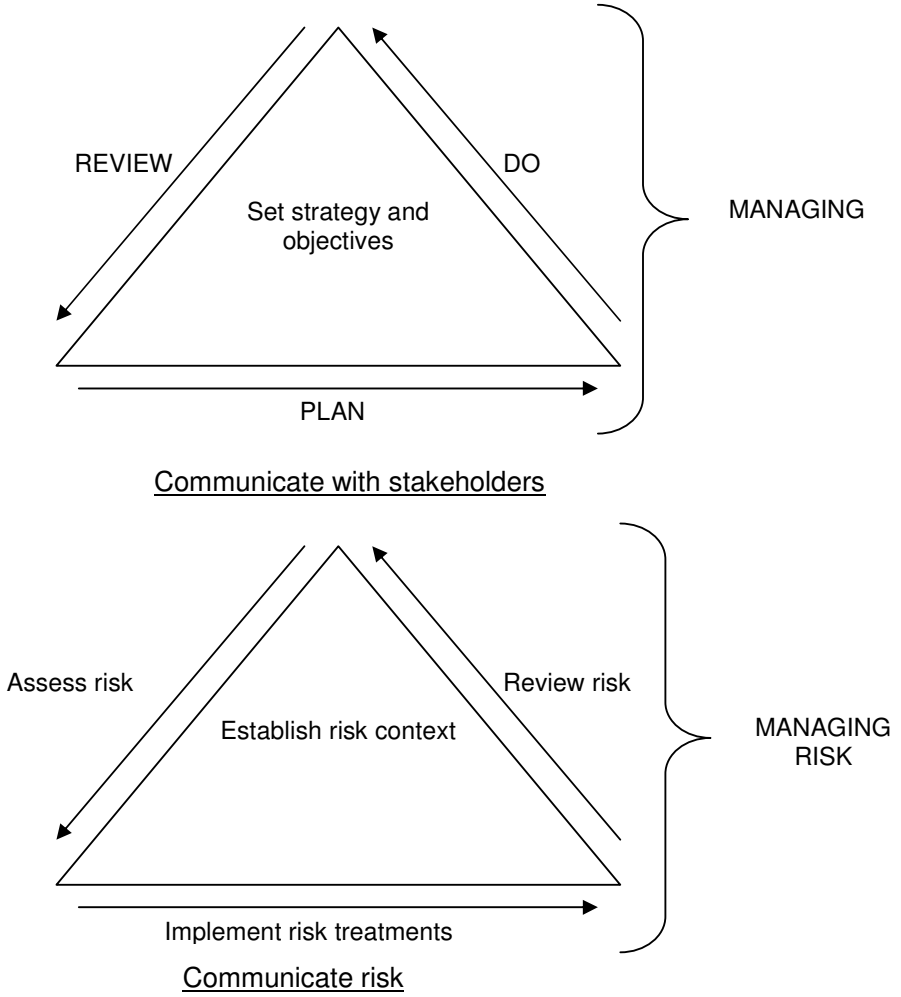

Figure 6.1: The risk management process
Source: Garlick, 2007: 16

Caddell, Crepinsek and Klanae (2004: RISK.01.1) have broken down the risk assessment process into the following categories:

Step 1 - Review: Key activities in this step include familiarisation of the project, formal review of the cost estimate and/or schedule and kick-off meeting (Jambhekar & Weeks, 2007: OWN.02.1).

Step 2 - Identify: All project risk should be identified as well as the project's key cost elements (Carlos & Formosco, 2006: 76). This process step is most important in setting the appropriate foundation for subsequent modelling and simulation.

Step 3 - Model: Although the risk analysis consists of applied probability and statistics, the creation of a cost or schedule model is the "art" of the effort (Sakka & El-Sayegh, 2007: 124). Herath & Kumar (2007: 307) point out that the model must define all the key dependent and independent variables and how the project risks affect them.

Step 4 - Range: The results of the risk analysis are influenced by the range of possible variation in cost elements and schedule activity durations (Borysowich, 2007: 06 June 2008). The objective of this step is to gather sufficient knowledge for the project participants to adequately define the optimistic, most likely and pessimistic view of variations to cost elements or schedule activity durations.

Step 5 - Simulate: Computer software packages are available to simulate risks, mostly making use of the Monte Carlo analysis process (Vargas, 2004: CSC.16.2). More detail is given on this process later in this study.

Step 6 - Summarise: The ultimate deliverable of the risk assessment process is to be able to produce a report that summarises the sensibility and simulation results, as well as an expert interpretation of the results.

Ker-Fox (2004: 2) comments on the risk management process followed by the Pebble Bed Modular Reactor (PBMR) in the planning of the nuclear power plant at Pelindaba (South Africa). Figure 6.2 depicts the process. Here risk and opportunity are identified within the project scope. To mitigate risk, the development, implementation and monitoring of control strategies are implemented and systems for communicating risk information within the organisation are developed.

2.3 Risk analysis

Risk analysis occurs after risk assessment so that when dealing with risk analysis, the risks should be well developed, but unprioritised. Patterson (2006: IT.05.1) points out that the key aspect of risk analysis is to be able to assign likelihood and consequence to each specific risk. There are two choices: either do it qualitatively, or with numbers (i.e. quantitively).

Lofton and Coppo (2007: RISK.05.1) point out that risk analysis is important to be able to consistently predict the final costs in projects. Estimates are developed in various stages of the project. The earlier in a project an estimate is developed, the more incomplete the information will be. With the incomplete information comes risk (Humphreys, 2004: 5).

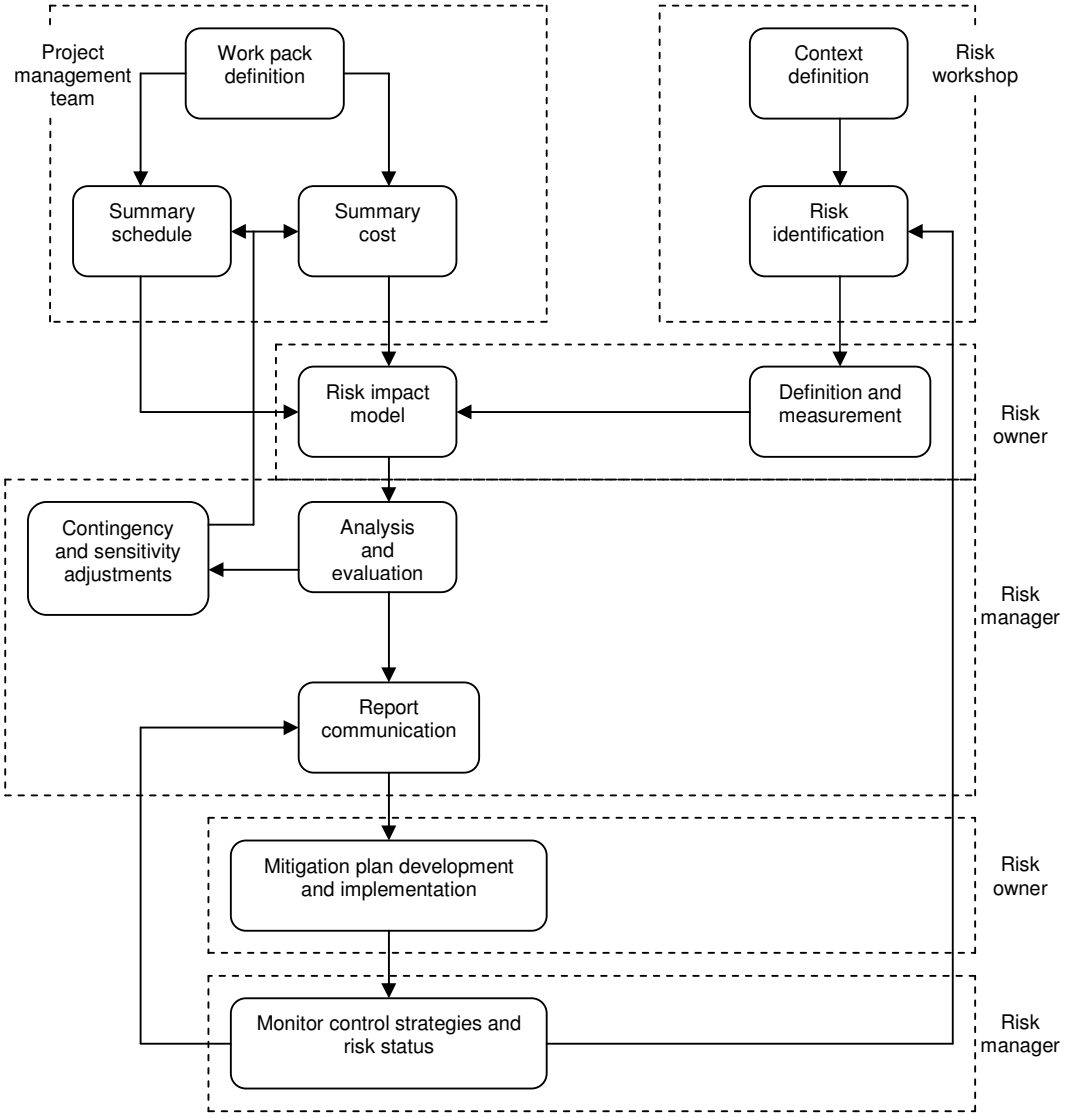

Figure 6.2: PBMR risk management process
Source: Ker-Fox, 2004: 3

Many of the pitfalls and difficulties in developing and interpreting risk analysis can be overcome by using an interview risk analysis (Lofton & Coppo, 2007: RISK.05.1). This type of risk analysis utilises answers to questions to drive the statistics. The questions that are asked relate to the ultimate risk exposure on the project. In the traditional risk

analysis, a question might be asked, e.g. “How much higher could the piping quantities be?” In an interview risk analysis, the question would be asked in a way that relates to scope, with a definite answer (Mulambya, 2007: RISK.08.1). It may be asked as multiple questions, such as, “Does the project have Issued for Construction (IFC) drawings, and/or does the project have IFC plot plans?” The answers to these questions have definite “yes” or “no” answers. The answers to these questions determine the potential for increase or decrease from the estimated value. Risks will be derived from these questions and these risks can be tabulated in a “risk register” as illustrated in Figure 6.3.

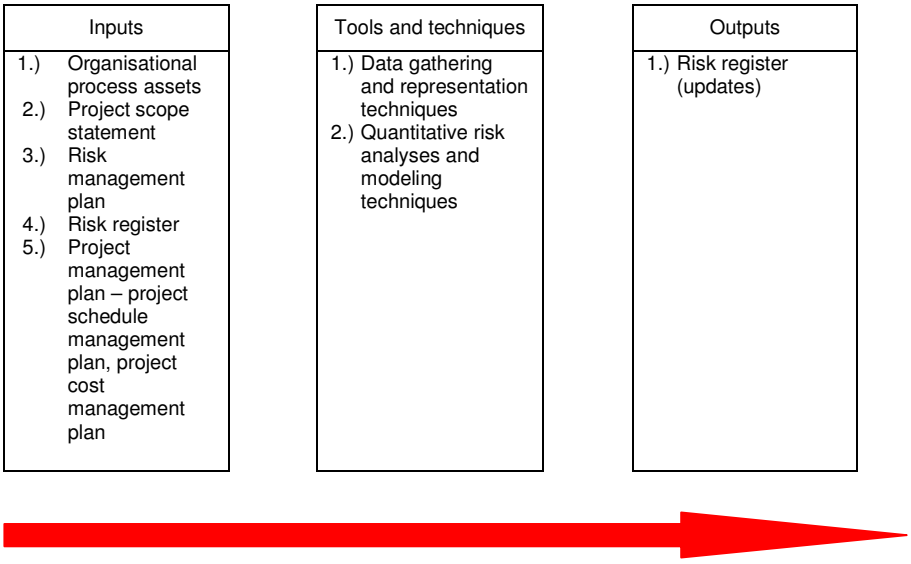

Figure 6.3: Quantitive risk analysis: Inputs, tools and techniques, and outputs

Source: Mulambya, 2007: RISK.08.1

Patterson (2006: IT.05.03) refers to the drivers of cost risk and how these drivers influence cost and why they should be considered when assessing the risks involved. Patterson states that controlling project cost is a science unto itself and a highly sought after project management skill. Add to this the complexity of risk and uncertainty and the situation becomes even more involved. Miscalculate cost estimates at the bidding phase and the enterprise runs the risk of entering into a loss-making venture. Mismanage cost overruns due to uncertainty during the execution of the project and “…the best laid plans fall to the wayside…” The following can be seen as general risks when pricing a project:

Duration of tasks – Lu and Anson (2004: 218) state that normally loaded resources, i.e. rate-based resources that are assigned to tasks, are going to incur varying costs to the project as the task duration changes. If a task takes twice as long as planned, the cost of the task is going to double if it has been assigned a rate-based resource (Chau, 1998: 42). Fixed cost resources are not impacted by varying task durations.

Resource rate/cost – Both fixed and rate-based resources costs are dependent on their respective cost values (Templeton, 2006: IT.03.1). A task with a rate-based cost is going to vary in cost not only due to variations but will also be dependent on the value of the resource rate.

Resource burn rate and number of resources required – Burn rate risk is typically driven by the need for more resources to complete planned work than originally expected (Voss, Sirdeshmukh & Voss, 2008: 155). If two bricklayers have been assigned to a task and it turns out that three are required in order to complete the task before a given deadline, then further costs will be incurred.

Uncertainty of scope – Poorly defined and managed scope is the most significant reason for project failure. To further add to the complexity of cost uncertainty due to the above drivers, uncertain scope can lead to further cost overruns (Wallwork, 2007: CDR.07.1).

2.4 Monte Carlo analysis

Monte Carlo analysis uses the process of simulation to achieve a range of solutions to a problem (Koller, 2005: 157). This technique is generally used to solve problems for which the definition of specific solution equations to calculate a specific answer is either too complex or too cumbersome to be practical (Verschoor, 2005: RISK.10.1). In Monte Carlo analysis, input variables are typically represented as distributions of values. Values comprising these distributions represent the range and frequency of occurrence of possible values for the variables. Monte Carlo analysis is a statistical procedure based upon random selection or chance (Whiteside, 2008: EST.04.2). The name Monte Carlo is taken from the city Monte Carlo (in Monaco) made famous by the games of chance.

Monte Carlo analysis or distribution sampling was arguably first presented formally by Student in the early 1900's. At first, Monte Carlo analysis was treated as being distinct

from experimental sampling or model sampling, both of which involve random selection from populations. Vrijland (2005: DEV.06.1) points out that the term Monte Carlo was restricted to processes in which weighted or importance sampling was used to increase the efficiency of the sampling process. The restricted use of the term later faded because high-speed computers lessened the importance of an efficient sampling process (Al-Sudairi, 2007: 112).

Koller (2005:157) states that today, the term Monte Carlo analysis can be applied to any procedure that uses distribution-based random sampling on approximate solutions to probabilistic or deterministic problems. These types of problems were exemplified by the first practical use of Monte Carlo analysis – addressing the probabilistic aspects of particle diffusion associated with the design and construction of the first atomic weapons at Los Alamos during World War II. Monte Carlo analysis was also used in the development of nuclear weapons.

2.4.1 The concept of Monte Carlo analysis

In a sense, Monte Carlo is a form of a repeatable experiment. Garlick (2007: 195) offers the following basic procedure that predicts the outcome of a Monte Carlo analysis.

- Take a sample from each of the input distributions.
- Work out the output(s) from the set of inputs.
- Do this as many times as needed.
- Turn the set of outputs into a distribution and estimate the properties needed, such as mean, variance, percentile, etc.

The strength of Monte Carlo lies within the fact that should one require a more accurate answer, the number of samples can be increased (Anjaneyulu, 2009: 12). If the goal is to calculate, for instance, the expected value of a total project cost, the mean of the values obtained from each simulation can be calculated.

Whiteside (2008: EST.04.1) also comments on the use of Monte Carlo analysis. Extrapolations or forecasting beyond or outside the known data realm has challenges, unless the data follows a normal trend or pattern (Whiteside, 2008: EST.04.1). It will be safe to use a trend line to calculate the next point past the last known data point

because it is still close to the known data. However, there is a need to forecast and make a reasonable prediction far beyond the last data point in many business decisions (Vargas, 2004: CSC.16.1). Predicting a point that is well beyond the last data point requires a good extrapolation routine. This numerically-based routine should be combined with other parameters to produce a range of probable outcomes that can be individually evaluated to assist with the decision-making process (Guggemos & Horvath, 2006: 188).

It is a basic tenet of forecasting that forecast data is always wrong because it is not "actual" data (Lowe & Skitmore, 2001: 488). A forecast may only be correct if the base assumptions continue to exist in the future. However, most people treat a forecast as nearly factual without updating the basis. Lowe, Emsley and Harding (2007: 18) point out that forecasts generally should guide and educate decision-makers about how the market reacts when certain assumptions and data (independent variables) are considered. Skitmore and Drew (2003: 38) state that a reliable forecast tool should include the following factors:

- Establish forecasting principles.
- Use of parameters to characterise the historical data.
- Near-term market conditions.
- Data-driven methods.

Probability is a way to bracket the volatility of short-term forecasts (seemingly random data). Monte Carlo analysis is a specialised probability application that is no more than an equation where the variables have been replaced with a random number generator (Noor & Tichacek, 2004: RISK.04.2). Skitmore (1986: 33) and Barraza, Back and Mata (2004: 27) state that the downside of Monte Carlo is that is more trusted than historical data. This misplaced trust is rooted in the idea that if a person has no historical data, then the Monte Carlo forecast can be anything that is believed plausible. It must be remembered that a Monte Carlo analysis is nothing more than an approximation. Few companies have the data available to support the distributions applied to the contingency elements (Whiteside, 2008: EST.04.1).

Hollmann (2007a: RISK.03.6) provides three main reasons why Monte Carlo techniques for contingency fund estimation sometimes do not work:

- Users are not addressing dependencies between model variables.
- They are not modelling the relationship risk drivers to cost outcomes.
- They fail to recognise the differences between systematic and project-specific risks.

3.0 INFLATION

3.1 Definition of inflation

Inflation may have positive and negative effects on an economy (Lundberg, 1977: 23). Negative effects of inflation include loss in stability in the real value of money and other monetary items over time, uncertainty about future inflation that may discourage investment and saving, and high inflation that may lead to shortages of goods if consumers begin hoarding out of concern that prices will increase in the future (Karpetis, 2008: 208). Positive effects include a mitigation of economic recessions and debt relief by reducing the real level of debt (Atkeson & Kehoe, 2007: 65).

Economists generally agree that high rates of inflation and hyperinflation are caused by an excessive growth of the money supply (Faig & Jerez, 2006: 3). Views on which factors determine low to moderate rates of inflation are more varied. Low or moderate inflation may be attributed to fluctuations in real demand for goods and services, or changes in available supplies such as during scarcities, as well as to growth in the money supply. However, the consensus view is that a long sustained period of inflation is caused by money supply growing faster than the rate of economic growth (Anwer & Sampath, 2001: 412).

Today, most mainstream economists favour a low steady rate of inflation (Hansen, 2007: 5). Low (as opposed to zero or negative) inflation may reduce the severity of economic recessions by enabling the labour market to adjust more quickly in a downturn, and reduce the risk that a liquidity trap prevents monetary policy from stabilising the economy. Phelps (2007: 454) states that the task of keeping the rate of inflation low and stable is usually given to monetary authorities. Generally, these monetary authorities are the central banks that control the size of the money supply through the setting of interest rates, through open market operations, and through the setting of banking reserve requirements (Lorenz & Lützkendorf, 2008: 483).

Inflation originally referred to the debasement of the currency. According to Hsieh and Klenow (2007: 563), when gold was used as currency, gold coins could be collected by the government, melted down, mixed with other metals such as silver, copper or lead, and reissued at the same nominal value. By diluting the gold with other metals, the government could increase the total number of coins issued without also needing to increase the amount of gold used to make them. When the cost of each coin is lowered in this way, the government profits from an increase in seigniorage. Seigniorage is the net revenue derived from the issuing of currency (Hsieh & Klenow, 2007: 563). This practice would increase the money supply but at the same time lower the relative value of each coin. As the relative value of the coins decrease, consumers would need more coins to exchange for the same goods and services. These goods and services would experience a price increase as the value of each coin is reduced.

By the nineteenth century, economists categorised three separate factors that cause a rise or fall in the price of goods: a change in the “value” or resource costs of the goods, a change in the “price of money” which then was usually a fluctuation in metallic content in the currency, and currency depreciation resulting from an increased supply of currency relative to the quantity of redeemable metal backing the currency (Olivei & Tenreyro, 2007: 637). Chen, Imrohoroglu and Imrohoroglu (2006: 1850) indicate similar findings. Following the proliferation of private bank note currency printed during the American Civil War, the term "inflation" started to appear as a direct reference to the currency depreciation that occurred as the quantity of redeemable bank notes outstripped the quantity of metal available for their redemption (Weiman & James, 2007: 276). The term inflation then referred to the devaluation of the currency, and not to a rise in the price of goods.

Parkin and Swoboda (1977: 4) believe that the question of what actually causes inflation is in all probability an unanswered one. O’Brien (2002: 12) also reports on this statement. He says that the reasons for this are firstly that the term inflation is too ill-defined and secondly, that there are too many links in the probable cause of inflation leading to the proposition of “everything depends on everything else”. Frisch (1977: 109) attempts to describe inflation as follows:

> *“…inflation is a monetary phenomenon for the explanation of which the quality of money is fundamental.”*

Eder (1979: 7) quotes the words of William Cobbett, who wrote in his book *The Curse of Paper Money* (1833); "Of all the instruments of mischief that the Devil ever invented, nothing was ever equal to the paper money". Eder (1979: 8) refers to "money illusion". He states that when it comes to inflation, there seems to be an illusion that prices are going up, but in reality it is the value of money that decreases (Davis & Figgins, 2009: 196). Eder makes the following strong statement:

> *"The problem is not one of rising prices, but the debasement of the currency."*

Eder (1979: 8) makes mention of the changing of the price of gold by Franklin Roosevelt from $20.67 an ounce to $35 an ounce. This changed the intrinsic value of the dollar from 1/20 of an ounce to 1/35 of an ounce. Presidents Nixon, Ford and Carter followed suit. This forced the dollar's value down, and thus it could buy less.

Lodewijks (2002: 122) refers to Professor Irving Fisher of Yale, whom many consider to be the greatest American economist who ever lived, who wrote a book under the title *The Money Illusion*. In it, Fisher described his 1922 visit to Germany at a time when the German mark had dropped to 1/50 of its former value. No one he met seemed to be conscious of the fact that the value of the mark had been dropping at a vertiginous rate. Everyone spoke of the unconscionable rise in prices (Karanasos & Schurer, 2008: 266).

It was easy enough for foreigners to see that the mark was being depreciated, but to the Germans a mark was a mark. Businessmen figured their costs in marks and sold their goods at what they thought was a profit (Arize, Malindretos & Nam, 2005: 462). They failed to realise that the marks they got for their goods were only one fiftieth of the marks that they had paid for it. It was not until the mark began to drop to one millionth and finally to a trillionth part of its former value that they began to realise that a mark in itself was no longer a mark (Rusek, 2008: 192).

Frankel and Burdzy (2005: 1) state that recessions and expansions often occur without any large precipitating shocks. An explanation for this is that with externalities, there can be multiple equilibria, so the path followed by the economy can depend on agent's expectations. These expectations can shift unexpectedly when payoff-irrelevant variables are observed, causing a recession or expansion. Baliamoune-Lutz (2008:

424) mentions specific cases in North Africa of how expectations can shift, and the effects thereof.

When dealing with inflation it is important to note that the increase in prices does not necessarily constitute inflation. Eder (1979: 10) puts it as follows: "No one is concerned with the facts that some 600 years ago one could buy a cow for a shilling, or that two loaves of bread could be had for a farthing." He stresses that the costs of commodities should rise rapidly to be classified as inflation. To Eder inflation can be described as follows:

> *"Inflation, then may be defined as an increase in the general price level for goods and services occurring over a relatively brief period of time."*

In every country where inflation has become deep rooted, businessmen have complained of a shortage of working capital and investment capital (Lomax, 2005: 252). They have failed to realise that the profits they show on their books are not truly profits and that when they have paid out dividends from these pseudo-profits, they have been eating into their capital – all because of the debasement of the currency. For the individual, inflation robs him of all incentive to save and to provide for the future (Karpetis, 2008: 206). Yet thrift is the basis of investment and investment is the foundation of economic growth and prosperity (Clemens, 2008: 181; Anwer & Sampath, 2001: 413).

Eder (1979: 38) states that there is no connection between employment and inflation, but there is a distinct connection between government deficit spending and a rise in prices. The more the government spent, to the extent that the extra spending came from government borrowing and was not taken from the citizens through taxation, the greater the money supply and hence the demand for goods, and the higher the prices would rise – demand-pull inflation (Lomax, 2005: 253). Fearon (2009: 122) supports this statement.

Six centuries ago, William of Ockham (1285 – 1349) laid down as a rule of logical reasoning the "law of parsimony," the principle that no more causes or forces should be assumed than are necessary to account for the facts (*pluralites non est ponenda sine necessitate*) – complexity must not be assumed without necessity. If there are several possible explanations of any fact or phenomenon, the simplest and most obvious explanation is most likely to be the valid one.

Facts show that, except in times of war or war's aftermath, there is no correlation between a rising price level and low unemployment (Eder, 1979: 39). From the beginning of recorded history, war has always brought scarcities, high prices and high employment – a correlation that is obvious, simple, logical and "parsimonious" (Ye, Zyren, Blumberg & Shore, 2009: 38).

3.2 Kinds of inflation

Eder (1979: 11) describes two kinds of inflation: wage-push or cost-push inflation and demand-pull inflation. With cost-push inflation, wages and other costs go up faster than the increase in labour productivity (Gupta, 2007: 337). Cost-push inflation is nearly always gradual and never reach the extremes that demand-pull inflation sometimes attains.

Demand-pull inflation is generally described as too many dollars chasing too few goods. In other words, there is too much money to spend and very little increase in the quantity of goods or services. In part, demand-pull inflation stems from wage increases (Gransberg & Diekmann, 2004: RISK.08.1). Wage earners have more money to spend and they spend it. This causes a spiral and in the economy any spiral (up or down) is vicious. Bojanic (2008: 501) and Jones (2001: 2) state that the general effect of wage increases on demand-pull inflation is seldom serious. It can almost always be rectified by an increase in production on farms, mines and factories. It is when demand-pull inflation is the result of government spending and deficit budgets financed with printing-press money that it can come with such extreme rapidity that it totally disrupts a nation's economy (Faig & Jerez, 2006: 4).

3.3 Historical methods used to fight inflation

Jacques Rueff (1963) was a French economist and adviser to the French government. He was considered to be an influential French conservative and free market thinker. He made the following statement regarding West Germany's post-war economic recovery:

> "*The suddenness of Germany's recovery was even more striking than its scope. It was not spread out over months or even weeks, but it had a specific date… the day the currency reform went into effect. Only those who were on the spot can bear witness to the literally instantaneous*

effect it had upon the reappearance of merchandise and customers in the stores."

This instantaneous end to inflation and the beginning of economic recovery in West Germany, pointed out by France's leading economist of the time, has been true in every country that has dared to face squarely the problem of uncontrolled inflation (Jones, 2001: 2). A gradual approach, the slow tapering off of inflationary pressures, has never worked, and indeed has only tended to make matters worse.

Eder (1979: 72-73) refers to people like Hjalmar Horace Greeley Schacht in Germany after World War I and Ludwig Erhard under the inspiration of his mentor, Dr. Wilhelm Röpke, after World War II, in describing how inflation was conquered almost overnight. Insights from the accomplishments of other people like Charles de Gaulle with the assistance of his economic adviser, Jacques Rueff; and those of Finance Minister Hayato Ikeda in Japan; of Gesualdo A. Costanzo, the United States Treasury adviser in Greece (1947); and of Princeton Professor Edwin Walter Kemmerer in eleven countries of the world, directed future dealings with inflation.

Following World War II, Dr. Ludwig Erhard was prohibited from altering the price controls imposed by the occupation economists. During a meeting with General Lucius Clay, head of the American mission, Erhard suggested the complete abolishment of all price controls in West Germany. This would have meant that prices would sky-rocket, but was nevertheless accepted.

The result was that Germany, on a free market basis and with a balanced budget, achieved one of the most remarkable eras of economic recovery that the world has ever seen, and as the late Dr. Rueff pointed out, the recovery was practically instantaneous. Economists of Keynesian beliefs argue that economic stabilisation only occurred because of the fact that excess money was withdrawn but the retirement of paper money, in Germany as elsewhere, was merely the final step in the stabilisation process (Villar, 2003: 2; Johnson & Cate, 2006: 115; Kates, 2002: 464).

The government exchanged one new Deutschmark for 100 old Reichsmarks and retired the old bank notes completely from circulation, precisely as Schacht had done a generation earlier when he exchanged one new Rentenmark for one trillion old marks. This was merely a matter of convenience, because adding machines and pocketbooks

were not big enough to accommodate the hundreds or thousands or trillions of old money. It had nothing to do with the process of stabilisation.

To prove that the buying up of paper money is not the cure for inflation, one should look at the findings of American economists who have analysed the German miracle. This quote by Dr. Röpke is so pertinent to inflation today that it is worthy of inclusion here:

> *"… the German accomplishment was nonetheless – in economic terms – no miracle at all, if the essence of the reform of 1948 is clearly understood. The real miracle lay in the fact that, in this particular country and in a world still under spell of inflationism and collectivism, it proved possible politically and socially to return to the economic reason of the market economy and to monetary discipline…".*

Nelson (2005: 1) refers to the Great Inflation of the Seventies in the United States of America. He mentions the overestimation of the degree of productive potential in the economy. Monetary policy did not intentionally target either high inflation or a positive output gap, but nevertheless pursued what *ex post* appears to be an excessively expansionary policy, because policymakers were too optimistic about the economy's supply side.

Gibbons (2009: 3) and Zaborowski (2009: 42) refer to the current poor worldwide economic situation and why economic change is necessary. Stiglitz (2009: 281) makes the following statement regarding the current poor state of the American economy:

> *"These are exciting times: the worst economic crisis since the Great Depression, the first global recession in the new era of globalization, and a new president committed to restructuring national priorities, reforming our education, health, and energy sectors, eliminating some long standing distortions arising from corporate welfare, and restructuring our tax code."*

Boero, Smith and Wallis (2008: 1108) comment on the influences of such factors as mentioned by Stiglitz on inflation. Chow and Shen (2006: 131) comment on the influence of education on the economy of China.

3.4 Reasons for inflation

Jackson (2008: INT.S01.1) stresses that in recent years "drastic" price changes for certain commodities, such as steel and cement, have upset not only financial markets, but integrated economic entities along the value chain as well. China's appetite for resources to feed its rapidly expanding and transitioning economy is probably the most dominant factor in observed commodity price hikes of late.

Razzak and Timmins (2008: 74) state that the ratio rise in wage inequality (between skilled and unskilled labour) can be explained by the supply and demand for skills. The shortage of skills is driving up labour prices and the gap between skilled and unskilled wages has increased by 25% from 1979 to 1995.

In 1801 Thomas Jefferson wrote the following:

> *"What is necessary to make us happy and prosperous people? A wise and frugal government, which shall restrain men from injuring one another, which shall leave them otherwise free to regulate their own pursuits of industry and improvement, and shall not take from the mouth of labour the bread it has earned."*

Eder (1979: 169) found Jefferson's advice to be true in the sense that in modern times, government deficit spending and printing-press money outweigh all other factors combined in contributing to inflation. Gil-Alana (2009: 144-145) also refers to the effects of government funding on the economy. Eder mentions some contributors to inflation. They are:

Waste – Waste is the besetting sin of the modern way of life. New car models every year, new fashion on a frequent basis, full garbage pails at home, expensive throwaway wrappings, boxes, bottles, cans, etc. All these add to the cost of living (Yahya & Boussabaine, 2006: 6; De Silva & Vithana, 2008: 190).

Protective tariffs – Protective tariffs, like customs duties, are so high to bar many potential imports and thus produce no revenue. These tariffs, for example, make it possible for manufacturers to maintain high prices on goods produced in a certain country (Coenen, Orphanides & Wieland, 2004: 1).

Monopolies – Politicians and economists like to blame the iniquity of big business – the monopolies and oligopolies – for higher prices. In actual fact, collusive price rising is a rare exception (Kraay & Ventura, 2002: 1). Violations are widely publicised and denounced. As an example, one can look at General Motors, Ford and Chrysler – the typical examples of oligopoly. These companies will keep their prices as close as possible to their estimated costs. The industry is highly competitive and knows that a 10% price increase means an approximate 10% decrease in sales, hence lower profits **(**Chung, 2007: 65).

The cost of dying – Improved medicine and medical practices prolonged human life. This means that there are more elderly people today than some years ago (Kopczuk & Slemrod, 2005: 5). These people do not contribute to the economy and are in actual fact putting additional strain on the economy (Robson & Kaplan, 2007: 492).

Restrictions on production – Union regulations restricting the number of bricks a bricklayer can lay in one day or limitations on agriculture production placed on farmers by the government and paying them for not producing will increase prices (Donoghue & Wright, 2002: 219; Ruffo & Hague, 2007: 1586; Sommers, 2008: 353).

Unnecessary labour – Labour union requirements and government requirements cause millions of man hours to be wasted annually due to unnecessary administration and bureaucratic governance (Hanna & Gunduz, 2004: 728). These man hours are being drained from the capital market that could otherwise be channeled into new productive capacity with corresponding benefits in the form of higher employment, lower prices and increased economic activity (Tsai & Tsay, 2008: 130).

High wages – High wages do not mean high prices as long as labour works as hard and as well as it can and so long as wage increases do not outstrip the innovation, invention, good management and capital investment that add to labour's productivity (Horman & Thomas, 2005: 836). To a large extent, wage increases have been the consequence and not the cause of modern inflation.

High profits – High profits do not have a serious effect on inflation. Eder (1979: 172) mentions the example of the major oil companies in the 70s. Companies like Exxon, Mobil, Gulf and Texaco would have lain off

at least 630 000 employees if they did not make the 1½ cents per gallon of fuel sold as net profit. During the same time, Americans had to pay at least 14 cents per gallon of fuel in federal, state and local taxes (Varila & Sievanen, 2005: EST.19.1). Profits are essential as a stimulus to investment in new and more modern plants and hence a major factor in keeping down the cost of living (Grubb, 2007: 281).

Minimum wages – Union and government action to fix minimum wages makes for higher prices and unemployment which in turns mean higher taxes to care for the unemployed (Galloway & Jozefowicz, 2008: 292).

Corruption – One empirical fact about corruption readily suggests itself – that it is inversely related to a nation's per capita income and inflation (Osborne, 2006: 289).

3.5 Effects of inflation

An increase in the general level of prices implies a decrease in the purchasing power of the currency (Cohen & Einav, 2007: 747). That is, when the general level of prices rises, each monetary unit buys fewer goods and services. The effect of inflation is not distributed evenly, and as a consequence there are hidden costs to some and benefits to others from this decrease in purchasing power (Whalen, Gopal & Abraham, 2004: 774). For example, inflation lenders or depositors who are paid a fixed rate of interest on loans or deposits will lose purchasing power from their interest earnings, while their borrowers benefit (Zhang, 2005: 333). Individuals or institutions with cash assets will experience a decline in the purchasing power of their holdings. Increases in payments to workers and pensioners often lag behind inflation, especially for those with fixed payments (Fehr & Goette, 2007: 299).

Fisher (2002: 215) points out that increases in the price level (inflation) erodes the real value of money (the functional currency) and other items with an underlying monetary nature, that are priced in terms of money (e.g. loans, bonds, fixed pension payments). However, inflation has no effect on the real value of non-monetary items, items without a fixed price in terms of money (e.g. goods and commodities, like cars, gold, real estate).

3.5.1 Negative effect of inflation

Kydland (2006: 1373) points out that high or unpredictable inflation rates are regarded as harmful to an overall economy. They add inefficiencies in the market, and make it difficult for companies to budget or plan long-term. Inflation can act as a drag on productivity as companies are forced to shift resources away from products and services in order to focus on profit and losses from currency inflation (Squires, Reid & Jeon, 2008: 83). Uncertainty about the future purchasing power of money discourages investment and saving. Inflation can impose hidden tax increases as inflated earnings push taxpayers into higher income tax rates (Gravelle & Smetters, 2006: 2).

With high inflation, purchasing power is redistributed from those on fixed incomes such as pensioners towards those with variable incomes whose earnings may better keep pace with the inflation (Davig & Leeper, 2007: 610). This redistribution of purchasing power will also occur between international trading partners. Where fixed exchange rates are imposed, rising inflation in one economy will cause its exports to become more expensive and affect the balance of trade. There can also be negative impacts to trade from an increased instability in currency exchange prices caused by unpredictable inflation (Galf & Monacelli, 2008: 120). These are:

Cost-push inflation – Rising inflation can prompt employees to demand higher wages to keep up with consumer prices. Rising wages in turn can help fuel inflation (Johnson & Cate, 2006: 117). In the case of collective bargaining, wages will be set as a factor of price expectations, which will be higher when inflation has an upward trend. This can cause a wage spiral. In a sense, inflation begets further inflationary expectations (Akerlof, 2007: 7).

Hoarding – People buy consumer durables as stores of wealth in the absence of viable alternatives as a means of getting rid of excess cash before it is devalued, creating shortages of the hoarded objects.

Hyperinflation – Arize, Malindretos and Nam (2005: 462) refer to the case of Germany in the post-war era. If inflation gets totally out of control (in the upward direction), it can grossly interfere with the normal workings of the economy, hurting its ability to supply.

Allocative efficiency – A change in the supply or demand for a good will normally cause its price to change, signalling to buyers and sellers that they should re-allocate resources in response to the new market conditions (Meyerhoefer & Zuvekas, 2008: 23). But when prices are constantly changing due to inflation,

genuine price signals get lost in the noise, so agents are slow to respond to them. The result is a loss of allocative efficiency.

Shoe leather cost – High inflation increases the opportunity cost of holding cash balances and can induce people to hold a greater portion of their assets in interest paying accounts. However, since cash is still needed in order to carry out transactions, this means that more "trips to the bank" are necessary in order to make withdrawals, proverbially wearing out the "shoe leather" with each trip.

Menu costs – With high inflation, firms must change their prices often in order to keep up with economy-wide changes. But often changing prices is itself a costly activity whether explicitly, as with the need to print new menus, or implicitly.

Business cycles – Krebs (2007: 665) shows that, according to the Austrian Business Cycle Theory, inflation sets off the business cycle. Austrian economists hold this to be the most damaging effect of inflation. According to the Austrian theory, artificially low interest rates and the associated increase in the money supply lead to reckless, speculative borrowing, resulting in clusters of mal-investments which eventually have to be liquidated as they become unsustainable (Smets & Wouters, 2007: 587).

3.5.2 Positive effect of inflation

The following can be considered positive effects of inflation:

Labour market adjustments – Keynesians believe that nominal wages are slow to adjust downwards. This can lead to prolonged disequilibrium and high unemployment in the labour market. Since inflation would lower the real wage if nominal wages are kept constant, Keynesians argue that some inflation is good for the economy, as it would allow labour markets to reach equilibrium faster (Johnson & Cate, 2006: 117).

Debt relief – Debtors who have debts with a fixed nominal rate of interest will see a reduction in the "real" interest rate as the inflation rate rises. The “real” interest on a loan is approximately the nominal rate minus the inflation rate (Geweke, 2007: 61). Banks and other lenders adjust for this inflation risk either by including an inflation premium in the costs of lending the money by creating a higher initial stated interest rate or by setting the interest at a variable rate.

Room to maneuver – The primary tools for controlling the money supply are the ability to set the prime rate, the rate at which banks can borrow from the central bank, and open market operations which are the central bank's interventions into the bonds market with the aim of affecting the nominal interest rate (Eschenbach & Cohen, 2006: 13). If an economy finds itself in a recession with already low or even zero nominal interest rates, then the bank cannot cut these rates further (since negative nominal interest rates are impossible) in order to stimulate the economy – this situation is known as a liquidity trap (Kojima, 2007: 1028). A moderate level of inflation tends to ensure that nominal interest rates stay sufficiently above zero so that if the need arises the bank can cut the nominal interest rate.

Tobin effect – The Nobel Prize economist, James Tobin, at one point argued that a moderate level of inflation can increase investment in an economy, leading to faster growth or at least higher steady state level of income. This is due to the fact that inflation lowers the return on monetary assets relative to real assets, such as physical capital (Kraus, 2007b: 3). To avoid inflation, investors would switch from holding their assets as money (or a similar, susceptible to inflation, form) to investing in real capital projects (Anwer & Sampath, 2001: 414).

Gerald E. Ford, Jr. (1974) made the following statement regarding inflation at the time (Eder, 1979: 259):

> *"Inflation is our domestic Public Enemy Number One. A Government big enough to give you everything you want is a Government big enough to take from you everything you have."*

Eder (1979: 259 – 260) stresses the effect of overspending, over taxation and government borrowing. He states that any government engaging in these activities will follow in the footsteps of England, which since the inception of the dole and the national health insurance and other welfare schemes, has deteriorated into a fifth-rate power economically, after Russia, Germany, Japan and the United States, with the Arab states and China looming on the horizon. Eder goes on to say that should countries not learn from Germany, Japan, France and Switzerland, and realise the folly of expecting the government to provide everything (Meza & Quintin, 2007: 1), they will have to face the consequences.

Bruno, Di Tella, Dornbusch and Fisher (1988: 401) comment on two basic fundamentals in restoring a sound growth rate in the economy: the amount of resources available and the efficiency of their use.

In general, inflation causes a decrease in the purchasing power of the currency. The effects of inflation are, however, not distributed evenly and as a consequence there are hidden costs to some and benefits to others. The effects of inflation can have serious consequences for the profitability of a project, should it be misjudged.

4.0 CONSTRUCTION COST ESCALATION

In order to measure or manage escalation on construction projects, it is firstly important to understand the driving forces behind it (Morris & Wilson, 2006: CSC.06.1). The most important factor is that construction must be viewed as a commodity in itself, not a collection of commodities. Butts (2007a: EST.08.1) states that the selling price of a project is not the result of the sum of its inputs plus a profit, except in the very rare cases where all work, including sub-contracts, is procured through a cost-plus contract (Rossetti & McKeeman, 2008: 6). In all other cases, the selling price of a contract is determined by the bidders based on their opinion of the competition. At a very basic level, it simply needs to be $1 less than the next bidder. The sum of the input cost will provide a floor below which the bidder is normally unwilling to go, and so changes in input costs will influence bids to some degree. The ceiling is, however, set by the bidder's opinion of the competition (Smith, 2008: 08 February).

During the course of the estimate certain questions will be asked. Will materials be available during time of construction and at the price allowed for in the estimate? Will labour productivity match that of the estimate? Will sufficient labour be available? Ibbs (2005: 1219) comments on labour productivity and Fleishman (2004a: 19) on labour availability. As risk increases so too does the floor below which bidders are unwilling to go. Risk is difficult to estimate and few bidders do it systematically. Risk assessments are usually influenced by short term perceptions based on the latest news (Gransberg & Carlisle, 2008: EST.09.1).

Morris and Wilson (2006: CSC.06.1) suggest that escalation comes from the interplay of changes, real or anticipated, in input costs, perceptions of risk, and perceptions of the competition. In some cases it comes from real information, such as actual changes in the cost of critical materials like steel and copper. More often than not, it comes from

the formation of market opinions, which may or may not have a basis of fact. Olhager and Selldin (2007: 1470) indicate that, ultimately, the ability for contractors to raise prices depends entirely on the market conditions and the expectation that all bidders are increasing their prices. Increased input pricing and increased risk can influence that expectation and ultimately increase the prices. Van der Merwe (2008) comments on the escalation in price of the construction work at the O.R. Tambo Airport in South Africa and how the aforementioned escalation causes also plagued this project.

Hollman and Dysert (2007: EST.01.1) define escalation as changes in price levels driven by underlying economic conditions. According to Jackson (2008: INT.S01.1), escalation is a pronounced and continued increase in the cost basis of certain, specific economic production factors over time. Escalation reflects changes in price-drivers such as productivity and technology, as well as changes in market conditions such as high demand, labour shortages and profit margins (Graves & Sexton, 2006: 362). Escalation also includes the effects of inflation, but differs from inflation which is a general change in prices caused by the debasement of the value of the currency (Adams, 2004: PM.08.2). From an estimator's perspective, escalation is a unique "risk" cost that must be estimated. To further complicate the issue, price escalation varies for different capital components such as office and field labour, bulk materials and equipment. It also varies by region and procurement strategy. Labuske and Streb (2008: 66) researched the effect of technology on the competitiveness of German mechanical engineers in the pre-World War I theatre and how improved technology put the Germans in a better position than the engineers of the Allied Forces.

Touran and Lopez (2006: 853) suggest that the more realistic way to estimate escalation is to consider the uncertainty in the value of escalation factors. This uncertainty is a major contributor to the overall cost uncertainty and can be modelled using appropriate probabilistic models. This becomes even more apparent when modelling the escalation uncertainty in large multi-year construction projects (Marsh, 2007: 778).

Probabilistic approaches are the best for estimating escalation. Construction professionals are generally poorly equipped to estimate escalation (Scott & Harris, 2004: 730). This is probably because escalation is driven by macro-economic conditions, the study of which is a core skill of economists (Welfe, 2008: 169).
Butts (2007a: EST.08.1) comments that accurately forecasting escalation rates can play an important role in project profitability or viability, especially for large multi-year

construction and development projects. The estimator must predict the cost of goods or services that must be purchased in the future, perhaps many years from now (Wong, Cheung & Hardcastle, 2007: 477). If the prediction is wrong, it will lead to equitable adjustments due to contractor cost increases which will cause profitability to suffer.

The most difficult part of any cost estimation process is to determine how much escalation to apply to the estimate. The South African construction industry recently has seen a rapid escalation in prices, leaving estimators wondering whether this is a trend that will continue or merely a temporary aberration (Jordaan, 2004: 2).

Hollman and Dysert (2007: EST.01.1) discuss the recent changes in escalation rates and indicate in Table 6.2 how commodity prices in America have increased since 2003.

Commodity items	Price increase (06/03) to (06/06)
Diesel fuel	121%
Iron and steel	60%
Iron ore	41%
Non-ferrous metals	85%
Industrial chemicals	55%
Cement	32%
Metal tanks	29%
Heat exchangers	40%
Pumps and compressors	15%
Wire and cable	81%
Motors and generators	15%
Process control instruments	7%

Table 6.2: Price increases for selected commodities in the United States from 2003 - 2006
Source: Hollman and Dysert, 2007: EST.01.1

The increase in commodity prices made the owners react by immediately pulling every mining metallurgy and oil and gas project proposal off their shelves. Despite the

memories of the 1986 oil industry capital spending collapse, engineering of these projects added to the backlogs of the engineering and procurement contractors.

During 2004 and 2005, many estimators were at a loss as to how to price project cost items. Bid prices from fabricators, suppliers and contractors varied widely but were almost always higher than expected (Kashiwagi & Savicky, 2003: 290). Suppliers quickly became unwilling to provide fixed price quotations, and those who did, included high risk premiums in their prices. Escalation clauses became more standard in contracts. Adding to the problem, owners and procurement and contracting departments regularly changed their minds about strategies for dealing with the situation. Hollmann and Dysert (2008: EST.08.1) point out that in late 2003 and throughout 2004, process industry CAPEX investment and prices increased dramatically. Increases in Asian demand and limited global supply after years of under-investment were the primary causes.

Given the volatility and uncertainty, many estimators threw up their hands and prepared their estimates using 2003 prices and put all “price risk” costs in an escalation account, and few managers could agree with the appropriateness. Other estimators included pricing risk in the contingency account which further muddied this already contentious cost account (Kohl & Wulke, 2004: IT.03.1). Aggravating the confusion, the costs of many projects-in-progress started to rise and in 2006 news reached the press that increases of 50% could be expected (Butts, 2007a: EST.08.1). During this time business managers did not know what to believe anymore and fearful of escalation increases, they began to lean toward excessive escalation funding knowing that project returns (such as the Internal Rate of Return) would still look reasonable if they could bring the capacity on-line while sales prices were near their peak (Cesarone, 2007: 40).

4.1 The problem in using cost indices

Cost indices are frequently used in predicting escalation. The cost index devised by G. R. Carli in the 18th century in Italy compares the cost between periods for a fixed quantity of goods or services (Butts, 2007a: EST.08.1). The concept of the index may be useful in some industries, but of the many cost indices in use today, no single index completely represents the construction industry. These indices have the same problem – they are lagging indicators since they measure cost changes that have already occurred (Evensmo & Karlsen, 2004: CSC.14.4).

In addition, these indices cannot account for the substitution of one product with another. For example, contractors may buy aluminum wire when the price of copper wire rises dramatically, or when regional shortages cause soaring prices (Rad & Levin, 2004: PM.07.2). Since cost indices track specific goods or services, if others are substituted, the rate of escalation measured by the index will be incorrect.

Hollmann and Dysert (2008: EST.08.2) state that periodically in 2005 through 2006 economists and the press reported that general pricing levels were about to level off or decline based on the assumption that asymptotic trends cannot be sustained for long (i.e. markets will correct over time). Hollmann and Dysert (2008: EST.08.2) point out the "short sightedness" of many in the construction industry during the time was evident in reports such as "…construction's inflationary cycle turned the corner during 2006 and will continue heading downhill through 2007 and 2008".

Mandel (2007: 23 April) was one of the economists who suggested that escalation will occur. In his article, Mandel suggests that the "…antiquated government statistics…" be overlooked and that the American economy should revert to consulting capital spending overseas.

4.2 Putting CAPEX indices to work

Process plant CAPEX (capital expenditure) is a micro-economy in which many prices are disconnected from what the government agencies and economists track (Hollmann & Dysert, 2008: EST.08.3). The prices that have become disconnected are for items and services whose prices are usually based on competitive bidding (usually with very few bidders in a tight market). Economists in general have trouble surveying bid pricing, especially where the product is not a constant (Roncaglia & Goodacre, 2008: 107). These bids include risk premiums, allowance for productivity changes, and other markups that are difficult to reliably measure or survey but can be reasonably predicted (Hollmann & Dysert, 2008: EST.08.3).

Hollmann and Dysert (2008: EST.08.3) suggest that the approach to the market challenge should be to adjust available wage and commodity pricing indices with a CAPEX market adjustment factor. For example, if CAPEX increases in a region by a drastic percentage in a year, then fabricators and contractors in the region will be able to increase their bid prices by a factor that is greater than the percentage increase in their underlying wages and commodities. Just how much they can raise their prices

depends on their market power. Hollmann and Dysert (2008: EST.08.3) use a simple exponent applied to the CAPEX increase. For example, if the underlying wages and other costs to a contractor increase by 8% (1,08), the market CAPEX increases by 25% (1,25), and the CAPEX exponent (or market power) factor is 0,5, then the typical price increase in the contractor's bid is calculated as follows:

Bid price increase = $1,08 \times 1,25^{05} = 1.08 \times 1.12 = 1.21$ or 21% increase.

The CAPEX exponent or factor may vary from zero (many suppliers just pass through costs) to 0,5 or 0,6 (few bidders). Each fabrication, contract, or other type of cost will have its own CAPEX factor that must be determined empirically or estimated based on experience.

The selection of indices will vary depending on the circumstances. First, the regional coverage of the selected CAPEX index must be applicable to the regional nature of the cost. Engineering and major equipment items are typically sourced overseas and are therefore driven by global CAPEX. Additionally, the CAPEX factor will vary by project size. For example, small projects will likely draw more competitive bids than mega-projects and therefore the CAPEX market factor will be lower for the small projects (Huot, 2008: OWN.04.2).

Figure 6.4 illustrates a comparison between how a traditional government based index such as the American Chemical Engineering Plant Costs Index - CHEPCI, with and without CAPEX adjustment, compares to the IHS CERA index (indicated here in annual cost factor format). The method described above requires the input of economists to provide base forecasts of traditional indices.

4.3 Construction escalation factors

Escalation or inflation is broadly defined as the change in the cost of a good or service over time (Gransberg & Diekmann, 2004: RISK.08.1). From an owner's perspective there is a problem with this definition, since it does not specify whose cost – the owner's or the contractor's? Most cost indices measure the cost to the contractor over a large geographical area and also fail to account for the difference in costing and pricing. Pricing is broadly defined as the cost the contractor bids for the project (Mochtar & Arditi, 2001: 405).

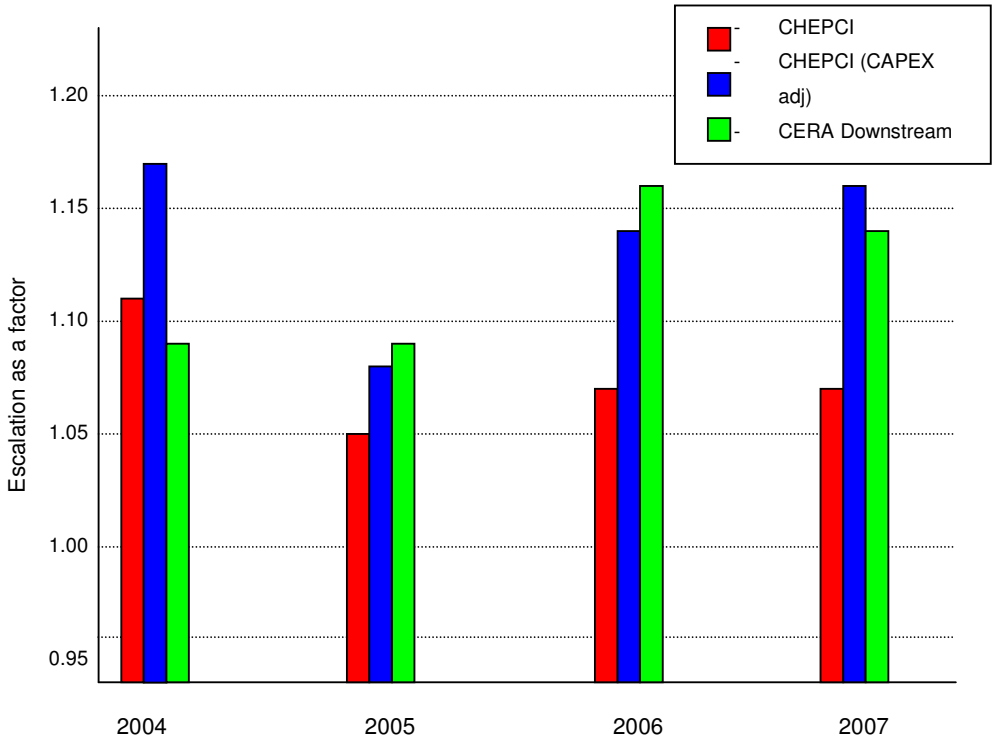

Figure 6.4: Comparison of the CHEPCI, CHEPCI (CAPEX adjusted) and the CERA Indices

Source: Hollmann and Dysert, 2008: EST.08.4)

This is why escalation should not be confused with local market conditions or demand surge as the insurance industry classifies it (Erasmus, 2004), although they both affect cost. Market conditions are generally additives to escalation. Categorised by specific local cost drivers like fear factors or opportunity cost increases, market conditions are usually limited to a local area or region. For example, market conditions may substantially increase local costs after a natural disaster; or during regional booms when contractors have more work than they need (Oo, Drew & Lo, 2007: 452; Schelling, 2006: 923).

An index is usually expressed as a percent change in price over a given time period, or as a representative of the price level at a given time (Hassanein & Khalil, 2006: 18). The primary source of historical price indices is government agencies. Economists study these historical trends and build econometric models that forecast future price index values, generally at a disaggregate level (Skitmore, 1991: 32). The models of price change for specific commodities are usually tied to macro-economic models that define the underlying economic conditions that drive all prices to some extent (Garratt, Koop & Vahey, 2008: 1129).

Morris and Wilson (2006: CSC.06.1) discuss a number of factors influencing construction cost escalation. They point out that the major drives behind current escalation surges are major natural disasters, increase in material cost, bid market disruptions, high volume of construction work, and the regulatory climate. Upcoming issues which will increase the pressure on cost even further include coherence in the global economy, a growing demand for construction work, and a shortage of labour as more and more skilled workers retire without new workers replacing them (Buettner & Rincke, 2007: 537).

The hurricanes in America in 2005 damaged or destroyed roughly three times as much property as during a typical year (Morris & Wilson, 2006: CSC.06.2). This created a high demand for construction materials and labour. The total cost of reconstruction is in the range of 10 to 15% of the annual construction market in the United States. Recognising that reconstruction will take several years, the anticipated annual impact on construction activity due to reconstruction work is likely to be in the range of 2 to 3% per annum. Given that much of the work may not show up as an increase in construction volume, but as a displacement of other planned work, the overall impact of the hurricanes on construction cost is expected to be relatively small (Swanson, 2005: 64).

The effect is likely to vary by region within a country. In the gulf region of the United States of America, there is a high demand for construction services, leading to market increases in the cost of labour and materials and competition between contractors (Tirasirichai & Enke, 2007: 368). The effect has been less in other parts of the United States, however, most parts of that country can expect to experience shortages of labour and material as the reconstruction process ramps up. Touran and Lopez (2006: 853) proved this statement.

While it is expected that such disruptions are likely to be transient, the uncertainty over price and availability as well as the actual delays or difficulty in obtaining necessary materials can have a marked effect on schedule and productivity for projects, and thus lead to increases in overall project costs (Ciccarelli & Murch, 2008: CDR.04.2; Al-Gahtani, 2007: RISK.10.1).

Morris and Wilson (2006: CSC.06.2) point out that in the past few years a number of strategic materials like steel, wood, cement, copper, PVC pipe and oil have seen significant increases in cost, sometimes more than doubling in less than a year. Norrbin, Pipatchaipoom and Bors (2008: 188) also make mention of the cost of natural

resources and how this can influence prices. While much of the escalation leading up to 2006 had been blamed on these material cost spikes, it is worth noting that even a dramatic increase such as the steel price increase in 2004 had a relatively small impact in aggregate (Adilov & Smavati, 2009: 51).

The world price for raw steel more than doubled in price in less than a year in 2004, rising from around $300/TN to around $600/TN (Mayo & Nuryeva, 2006: EST.06.1). Even with the doubling in price, the overall direct impact on total building construction cost was actually small (Hagmann, Stoy & Terashima, 2008: INT.07.1). Taking into account all the steel in a building (typical American construction of high rise buildings include structural steel frames) - the structure, studs, doors, frames, ductwork, pipe work, etc. - buildings usually only use about 20 to 30 pounds of steel per gross square foot (GSF). For an increase of $300/TN, this translates into an increase of only about six dollars per square foot, or roughly 2 to 4% of a typical building. This alone cannot be enough to account for the dramatic rise in construction project bids seen during this time (Lomax, 2005: 252).

A frequently overlooked escalation factor is changes to code and practice in design and construction. Pulaski, Horman and Riley (2006: 84) discuss the correlation between design and construction. This includes changes in plant codes, changes in regulations, and controlling activities within plants. An example would be the changing requirements for bio-safety performance in research facilities and changes in the way buildings are used. While these changes can increase and decrease construction cost, studies show that these changes typically add only 1% per annum to the cost of construction in the long run (Morris & Wilson, 2006: CSC.06.2). Bilec, Ries and Matthews (2007: 266) point out the added cost due to green design.

While direct changes in the cost of material and labour have a relatively small impact on the cost of construction, the uncertainty over prices has created some disruption in the bidding environment (Nutakor, 2007: 10). Traditional bidding approaches place all risk of material and labour pricing at the sub-contractor level, where there is very little room to accommodate price movements (Acharya, Lee & Im, 2006: 548). Returning to the steel price increase in 2004 as an example, while a $300/TN increase created an increase of only 2 to 4% on the bottom line cost of construction, it was a 25 to 30% increase in cost to reinforcing steel contractors.

When material prices are fluctuating wildly, bidders cannot lock in prices at bid time. Suppliers are unwilling, or unable, to provide any price assurance for anything other than short term orders (Koushki & Kartam, 2004: 127). Delivery schedules are often extended because material demand is so high, as a result of high construction volume as well as panic-induced stockpiling of materials by contractors (Carbone & Tippett, 2004: 29). Contractors often have to pay premiums to expedite supplies, but to counteract the possibility of shortages or delays some bidders double or triple book orders, which only compounds the material shortages. Contractors are understandably nervous since typical bidding processes ask them to submit fixed prices for work that often may not even start for up to a year or more after the bidding period (Fang, Li, Fong & Shen, 2004: 853). Suppliers are sometimes even more nervous since they are asked to adhere to prices for materials which may cost more to obtain once construction actually starts (Williams, 2007: 343). Volatility therefore makes contractors more likely to build risk premiums into their bids to cover potential increases in material prices, and suppliers more likely to wrap material quotes with an additional premium to ensure that they will still be able to make a profit in case of spikes in material cost (Odeyinka, Lowe & Kaka, 2008: 7). These premiums are usually higher than the expected increase in overall material cost, making volatility a far greater cost inflator (Fang, Fong & Li, 2004: 862).

The current high volume of construction is creating a high demand for skilled construction workers (Esposto, 2008: 101). Townssend and Charles (2008: 65 – 65) had similar findings in the military sector. In cases where there is a severe shortage, there will be a reduction in the skills levels as a result of this. Even where demand for labour is not that high, worker availability is affected by the drawing of workers into the high demand areas (Srour, Haas & Borcherding, 2006: 1054). The shortages of skilled labour increase the contractor's risk by increasing the likelihood of delay and more punch list (snag list) and remedial work (Addison *et al.,* 2008: 116).

Where construction activity is high in a specific area, there usually is a high demand for construction services. If similar increased construction activities are experienced in neighbouring regions, it makes it difficult to draw contractors into the region from other areas. Premiums must then be paid to obtain contractors. These additional costs will influence the final cost of any development.
Hollmann and Dysert (2007: EST01.1) mention some additional factors influencing construction escalation:

Global demand – The global demand for commodities is greater than any other time in history (Stein, 2008: IT.02.2).

Energy costs – The costs of oil, natural gas, coal and electricity are major components of construction cost. Claasen (2008b: 04 July) mentions that costs are expected to continue to rise substantially as a result of the following:

Utility deregulation: Rates, which have been locked at an artificial low level for a number of years, are opening up to market pricing and large increases are expected.

Environmental regulations: Fears of global warming are driving retrofits of power plants, use of cleaner fuel, and pollution controls on new diesel equipment – all of which are expensive (Kulatunga, Amaratunga, Haigh & Rameezdeen, 2006: 60; Hao Hills & Huang, 2007: 15).

Aging infrastructure – Many of the power distribution systems in many countries are beyond their life expectancy. Replacement will be expensive (Park, Hwang, Seo & Seo, 2003: 27).

Instability in the Middle East – Crude oil and natural gas are used in the mining, production and transportation of many construction materials (Ye *et al*., 2009: 43).

Security requirements – New security requirements for background checks limit the available pool of workers.

Climatic changes – Worldwide increases in weather anomalies will consume certain regions' available resources. The explosion in development along the United States coastline can make the effect of a hurricane so much worse (Deschenes & Greenstone, 2007: 355).

Immigration policies – Illegal immigrants make up a large share of the labour pool (especially in America) in the construction industry. If there is a decrease in the use of illegal labour for construction, the competition for labour from legal sources will drive up costs.

Large scale expansion – A sudden dramatic increase in construction activities draw large portions of the available skilled labour, and will therefore drive up costs.

Hollmann and Dysert (2008: EST.08.1) state that escalation reflects changes in pre-drivers such as productivity and technology as well as changes in market conditions

such as high demand, labour shortages, profit margins, etc. Technological progress (such as information technology) and the influence it has on the economy change market conditions and may have an effect on escalation (Chung, 2007: 63; Jorgenson & Vu, 2007: 126).

5.0 MEASURING ESCALATION

Measuring inflation in an economy requires objective means of differentiating changes in nominal prices on a common set of goods and services, and distinguishing them from those price shifts resulting from changes in value such as volume, quality, or performance (Botti, Conte, Di Cagno & D'Ippoliti, 2008: 3). For example, if the price of a 10 oz. can of corn changes from $0.90 to $1.00 over the course of a year, with no change in quality, then this price difference represents inflation. This single price change would not, however, represent general inflation in an overall economy. To measure overall inflation, the price change of a large "basket" of representative goods and services is measured (Ball & Petrowski, 2007: EST.09.1). This is the purpose of a price index, which is the combined price of a "basket" of many goods and services. The combined price is the sum of the weighted average prices of items in the "basket". A weighted price is calculated by multiplying the unit price of an item with the number of those items the average consumer purchases (Flemming & Koppelman, 2009: 22). Weighted pricing is a necessary means to measure the impact of individual unit price changes on the economy's overall inflation. The Consumer Price Index (CPI), for example, uses data collected by surveying households to determine what proportion of the typical consumer's overall spending is spent on specific goods and services, and weights the average prices of those items accordingly. Those weighted average prices are combined to calculate the overall price (Flemming & Koppelman, 2009: 22). To better relate price changes over time, indices typically choose a "base year" price and assign it a value of 100. Index prices in subsequent years are then expressed in relation to the base year price (Hamood Al-Harthy, 2007: 280).

Inflation measures are often modified over time, either for the relative weight of goods in the basket, or in the way in which goods and services from the present are compared with goods and services from the past (Leishman & Watkins, 2002: 40). Over time adjustments are made to the type of goods and services selected in order to reflect changes in the sorts of goods and services purchased by "typical consumers". New products may be introduced, older products disappear, the quality of existing products may change, and consumer preferences can shift. Both the sorts of goods

and services which are included in the "basket" and the weighted price used in inflation measures will be changed over time in order to keep pace with the changing marketplace (Lum, 2004: 32).

Inflation numbers are often seasonally adjusted in order to differentiate expected cyclical cost shifts (Skitmore, Runeson & Chang, 2006: 777). For example, home heating costs are expected to rise in colder months, and seasonal adjustments are often used when measuring for inflation to compensate for cyclical spikes in energy or fuel demand. Inflation numbers may be averaged or otherwise subjected to statistical techniques in order to remove statistical noise and volatility of individual prices (Ramey & Vine, 2006: 1878).

Measuring and tracking cost escalation requires a reasonably accurate index based on information that is reliable and captures a wide enough spectrum of data that all aspects of escalation are covered (Bureau for Economic Research (BER), 2008b: 20 November 2008). There are several indices that can be used to measure construction cost escalation in South Africa. Several of these are specifically for the building construction industry and will not be discussed in this study. The indices mostly used in the engineering industry in South Africa include the Steel and Engineering Industries Federation of South Africa (SEIFSA) indices (SEIFSA, 2009: 06 August 2009).

SEIFSA (2009: 06 August 2009) points out that SEIFSA is the industry's voice in the Trade and Industry Chamber of the National Economic Development and Labour Council (NEDLAC). Most companies in the industry do not sell directly to consumers, but to national, provincial or local governments, private corporations or other companies in the industry, requiring inputs for their own production. Lead times between tender, order and delivery can be considerable – often a year or more (Hassanein & Khalil, 2008: 20). Therefore, and especially in times of high inflation, it is important for tendering companies to have a way of adjusting their contract prices to compensate for unforeseen cost increases in the period between tender and delivery (Hudson & Hudson, 2004: PM.22.2).

SEIFSA consults on Contract Price Adjustment (CPA) formulas and escalation calculations which allow tenderers to adjust delivery prices in line with unforeseen cost increases. This SEIFSA service assists companies to allow for price adjustment provisions that are fair and equitable to them as well as their clients. The value of this

service to companies is in excess of R7 billion a year in escalation claims on contracts (SEIFSA, 2009: 06 August 2009).

The monthly SEIFSA Price and Index Pages publish 140 indices that measure changes in the costs of manufacturing inputs in the industry. By including data from these indices in a CPA formula, a company can calculate the average changes in costs of labour, steel, transport and other inputs affecting the final cost of manufacture. SEIFSA regularly reviews the make-up of the various indices it generates in order to ensure that they remain relevant and accurate (SEIFSA, 2009: 06 August 2009).

Jackson (2008: INT.S01.2) states that the Production Price Index (PPI) data are commonly used in escalating purchase and sales contracts. These contracts typically denominate specific dollar amounts to be paid at some point in the future. It is often desirable to include an escalation clause that accounts for changes in input prices. For example, a long-term contract for steel may be escalated for changes in scrap metal prices by applying the percent change in the PPI for wheat to the contracted price for steel.

The PPI is a family of indices that measures the average change over time in selling prices received by domestic producers of goods and services. PPI's measure price changes from the perspective of the seller (Faig & Jerez, 2006: 4). This contrasts other indices, that measure price change from the purchaser's perspective, such as the Consumer Price Index (CPI). Sellers and purchasers' prices may differ because of government subsidies, sales and excise taxes and distribution costs.

It is important to evaluate cost indices to determine which provide the clearest and most consistent method of tracking what is happening to costs. Lomax (2008: 252) states that the evaluation criteria to consider include the following:

- Correspondence with true inflation – does it accurately reflect changes in construction cost?
- Cost to administer – what does the index cost to maintain?
- Objectivity – is the data free from subjective interpretation?
- Self-correcting – will the index be correct from year to year?
- Contribution of costs such as materials, labour, general conditions, market conditions, and codes and practices to the total calculated index.

Each index should be evaluated not only on the aforementioned criteria, but on how it is intended to be used for a particular project or process calculation. Those which include input not just from materials and labour prices, but also from general and market conditions, and code of practice impacts, can be reasonably expected to be more reliable (Jackson, 2008: INT.S01.2). Indices which are based on statistical information are more likely to be objective than those based on opinions or views of individuals. Saito (2004b: INT.01.2) points out that indices which track larger numbers of items or projects can be expected to achieve a greater accuracy and level of reliability since it is more likely that they will take into account a wider range of the variables that impact cost escalation in the current world market. However, these indices are often more complicated and costly to administer (Saito, 2004a: INT.02.3).

Hollmann and Dysert (2007: EST.01.4) provide the following criteria in selecting and developing price indices for use in escalation estimating:

- They should be based on industry or government sources that are generally recognised as reliable and are readily available.
- They should be generally applicable to the subject industry in the primary regions where a company performs or will perform capital projects.
- They should be specific to the major cost types.
- They must be easily updated, modified and maintained as an ongoing reference source.

In the long run cost escalation is passed on to the end-consumer in the form of higher prices and thus ultimately it “bleeds” into inflation and the CPI (Jackson, 2008: INT.S01.2). In order to adequately capture project cost information over time and ensure comparability among projects, some companies have established proprietary projects systems to track costs according to an established Cost Breakdown Structure by project type. Figure 6.5 illustrates the developing process of an appropriate index to track escalation.

5.1 Applying price indices to project costs

Elementary level price forecasts are relatively easy in the sense that after choosing the correct index, a current index is divided by a base index and then multiplied by the base rate (Al-Jibouri, 2003: 146). It is more of a challenge to determine the best way to

apply disaggregated indices to elements of the overall plant cost (for which no reliable aggregated forecast index is available).

The historical and forecast indices available are usually in a disaggregated format. In other words, there are separate indices for each of the major resources that go into or make up a project's cost structure (Musgrove, 2008: EST.07.2). The indices supplied by the Steel and Engineering Industries Federation of South Africa (SEIFSA) is a typical example. Here the price increases for copper, steel, etc. are shown separately in different index tables.

The estimator must then break down the project cost estimate into categories of cost of which applicable price indices are available (Ball & Petrowski, 2007: EST.09.3). This is not always a straightforward task. For example, a typical process plant has significant pipe material cost. Most of the piping material cost is for piping spools from the fabricator. The spool price includes for pipe, fittings and shop labour costs. The available disaggregated indices do not cover spool prices; therefore the estimator must create an aggregate or "proxy" index for the shop fabricated pipe that includes a weighted mix of pipe cost, fitting cost and the cost for shop labour (Hassanein & Khalil, 2006: 183).

Economists can provide hundreds of wage price and other price indices. As the estimator builds up weighted indices, or otherwise lines up cost categories with indices, there is the risk of going overboard with detail that can complicate the effort without adding real value or increased accuracy. For example, there may be wage increases for many different crafts, but in general they follow the same trend (Hassanein & Khalil, 2006: 183). Using one of these indices as a proxy measure for all crafts may be appropriate.

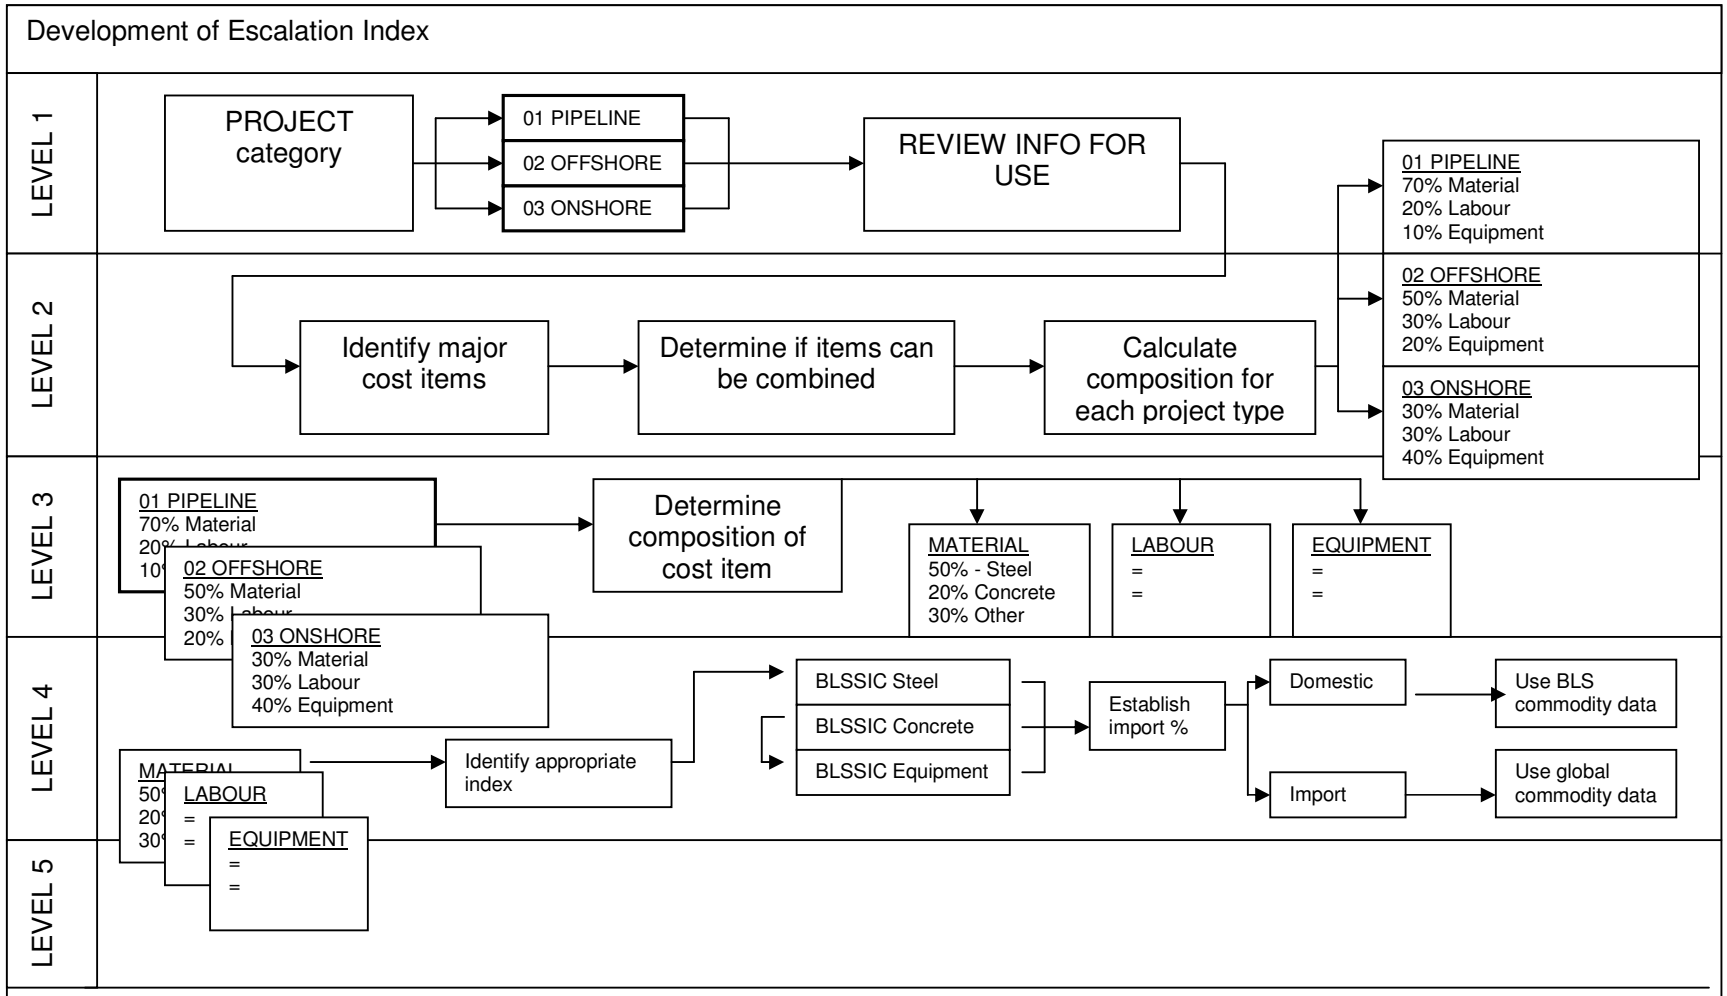

Figure 6.5: Index development chart

Source: Jackson, 2008: INT.S01.2

5.2 Required index components

Many escalation models fail either because of lack of appropriate detail and applicability to the business case, or too many complex routines for maintaining the escalation model (Jackson, 2008: INT.S01.3). In other words, the model needs to deliver the appropriate amount of information without becoming a burden and overweighing its benefits. Figure 6.6 is taken from several American projects to show their relevant cost composition.

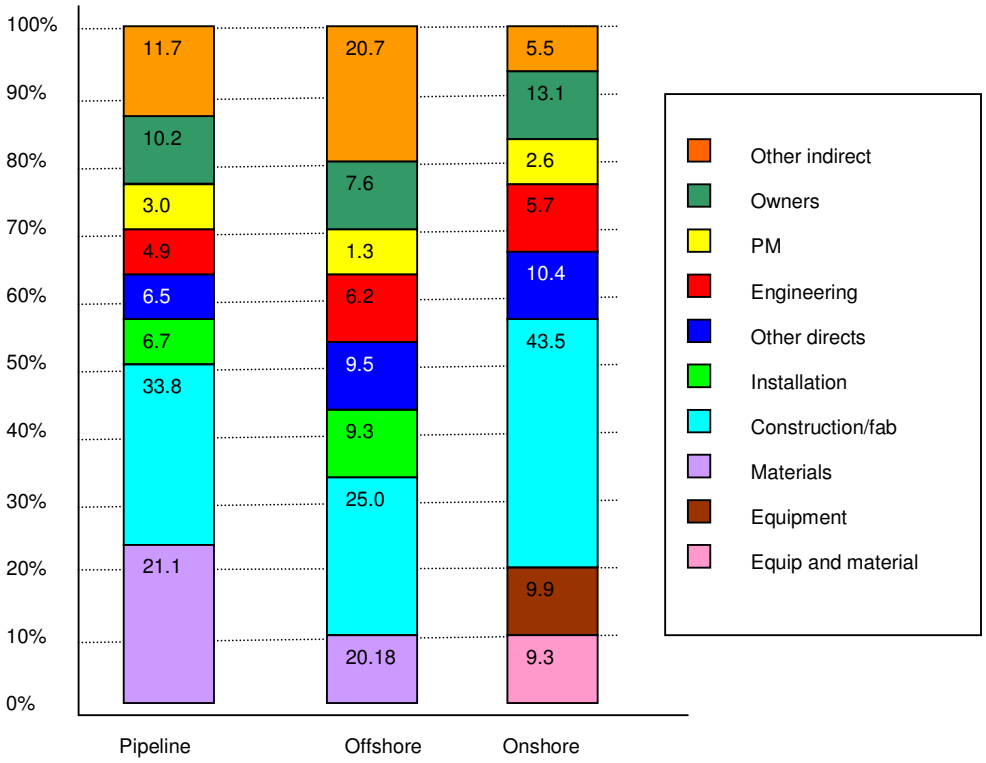

Figure 6.6: Cost composition by project type

Source: Jackson, 2008: INT.S01.3

Jackson (2008: INT.S01.3) identifies about ten distinct project cost types. Each of these cost types can be broken down into very specific categories. However, the level to which these costs should be broken down must be weighed against the perceived benefit that is gained from applying a more detailed set of escalation indices to an increasing number of cost types. In fact, several main cost types may actually be combined if the nature of their sub-costs suggests strong congruency.

Figure 6.7 illustrates a combination of “installation” and “fabrication” with labour being the main common sub-type. Table 6.3 displays the basic sources to arrive at

escalation factors. It is, however, recommended to consider adjustments to this model based upon specific requirements.

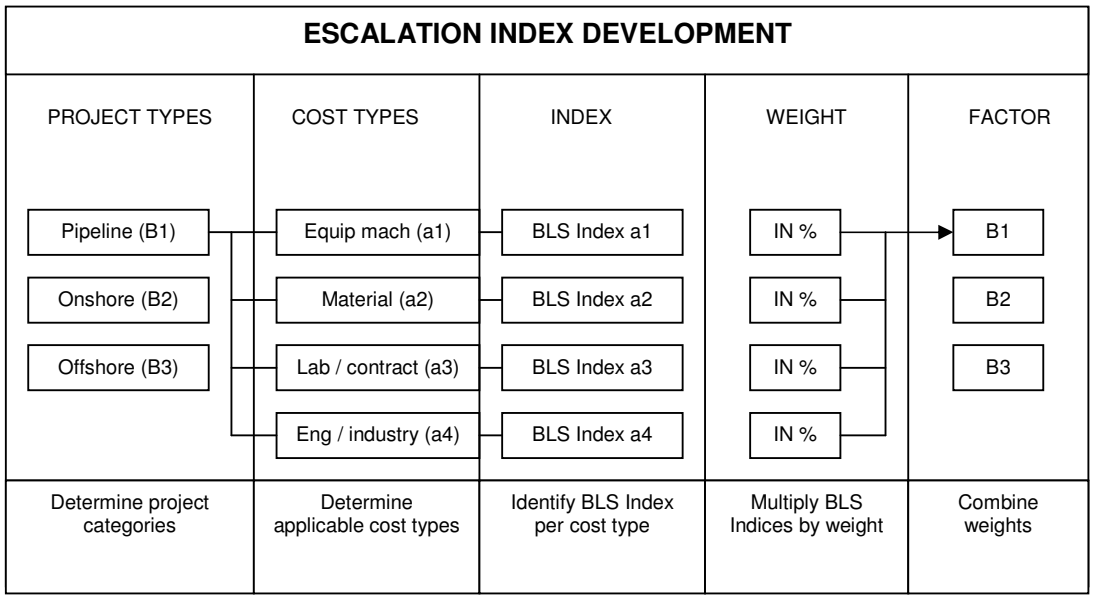

Figure 6.7: Simplified Index Development Model

Source: Jackson, 2008: INT.S01.4

COST	PIPELINE	ONSHORE	OFFSHORE	INDEX
Equipment and material + ODC	30%	30%	30%	50% Material IC332312-5 for pipeline (331210-0) 50% Equipment IC 333132
Construction, installation and fabrication	33%	42%	33%	BLS Index of hourly compensation costs for production workers
Engineering	5%	6%	6%	BLS IC 54133
Indirects	32%	22%	31%	Same as “Engineering”
TOTAL	**100%**	**100%**	**100%**	

Table 6.3: Tabular index weights and source

Source: Jackson, 2008: INT.S01.4

The indices in Table 6.3 are displayed in Figure 6.8. It is noticeable that a significantly directional change occurred in 2004 with cost increases in many major cost components but most visibly in steel or metal related commodities. The CPI does not display a considerable change in the degree of escalation for that particular time period, which may be the cause for disproportionate comparative results when assessing multiple time periods.

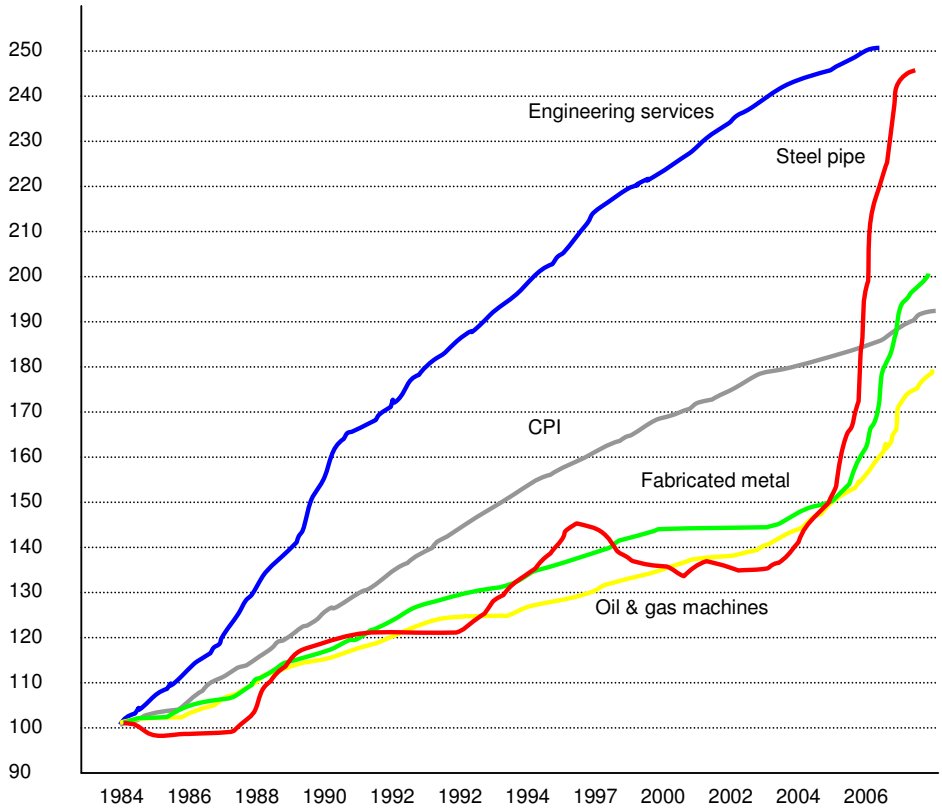

Figure 6.8: CPI versus Component PPI indices
Source: Jackson, 2008: INT.S01.05

Construction rates are made up of some components to cost the full complement of work relating to that specific activity. Labour, material, consumables and profit can be seen as the main contributors to cost on a project. Depending on the formula that is employed to calculate escalation, these components might be split up (kept separate) and then be escalated separately as there are different indices for the different material types and for the labour involved in the activity.

5.3 Modelling of a cost escalation factor

Touran and Lopez (2006: 855) define the cost escalation factor as the rate of change in the cost escalation indices form year to year and they propose the following formula to calculate this rate:

$\Delta_I = [(I_i / I_{i-1}) - 1] \times 100\%$

Where:

Δ_I - is the percent of change of period,
I_{i-1} - is the index of the previous period (i – 1),

A positive value of Δ_I is an indication of increase in cost. In contrast, if the value of Δ_I is negative, that is because period (i) has experienced a deflation. They compound the average value for Δ for a given period by using the following formula:

$r = [(I_e / I_b)I/n - 1] \times 100\%$

Where:

r - is the average rate of change,
I_e & I_b - are the index values for the beginning and end periods, and
N - is the number of periods between $_e$ and $_b$.

5.4 The effect of interest rates on escalation indices

Interest rates appear to have an inverse relationship with construction cost increases. Figure 6.9 indicates this tendency. When interest rates increase, the cost of financing construction rises, and the number of new projects gradually declines (Elizandro & Matson, 2007: 99). With less work, there is more competition for the available projects and a reduced demand for raw materials. Increases in interest rates generally precede a slowdown of the general economy, making companies less likely to fund large capital projects. On the other hand, if interest rates are reduced, the cost of financing construction is reduced, and the economy is generally poised for an upswing (Sanchez, 2008: 46).

5.5 The effects of EPC capital markets on cost indices

A challenge not mentioned before which also comes into play and that cost indices do not take cognizance of is the micro-economy. For example, the Engineering, Procurement and Construction (EPC) form of contracting is a micro-economy where the labour prices have increased more than the engineering and construction that the government agencies and the economists track. This is because contractors' prices include mark-ups such as risk premiums, productivity factors, etc. (Squires, Reid & Jeon, 2008: 82). No one tracks EPC bid prices per se. In the long run, underlying costs (such as wages) drive trends, while market strength can be the dominant driver in the short run (Hollmann & Dysert, 2007: EST.01.5).

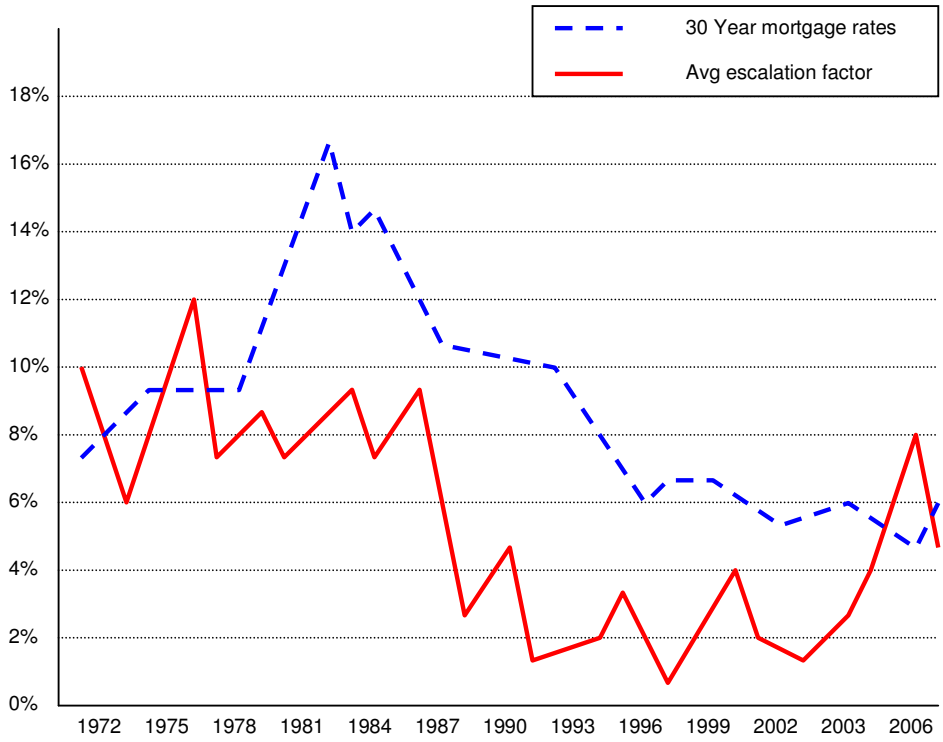

Figure 6.9: Cost indices compared to rates for 30 year fixed-rate mortgages
Source: Butts, 2007a: EST.08.2

Hollmann and Dysert (2007: EST.01.5) adopted the method of specific construction knowledge to that of the economist's macro-economic knowledge. They propose the adjustment of existing available labour pricing indices with additional factors that reflect the relevant level of capital expenditure in the EPC market. For example, if EPC investment increases substantially in a year, EPC contractors will be able to exert their

market strength and raise bid prices in some proportion to which the rate of capital spending increases.

Figure 6.10 illustrates how EPC engineering and construction prices for small and large projects tend to vary with the level of capital spending for process plants (which is a micro-economy).

Note that small project price trends vary less and EPC pricing level changes tend to lag changes in the economy. Hollmann and Dysert (2007: EST.01.05) make the following statement:

> *"There is no doubt that labour pricing is linked to the relative level of CAPEX in the process industries (and construction employment)."*

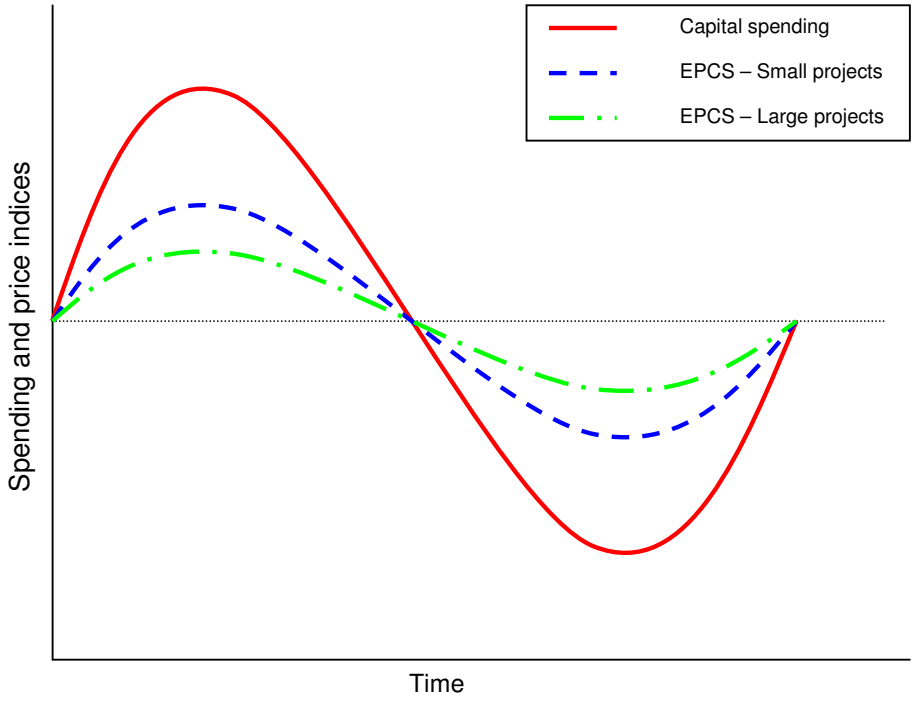

Figure 6.10: EPC labour prices vary with trends in capital expenditures
Source: Hollmann and Dysert, 2007: EST.01.04

The only uncertainty is the extent to which CAPEX affects labour price on a given project in a given region. Furthermore, the CAPEX effect is less on small projects using local contractors with long standing relationships. The effect is greatest on large projects – particularly those in more isolated areas with smaller labour pools. Hollmann and Dysert (2007: EST.01.05) mention Alberta in Canada as an example.

Factoring market demands into labour price indices is not yet common practice. However, it is necessary that this be done because published indices only cover compensation which tends to be fairly stable. They typically do not track the prices owners pay. Hollmann and Dysert (2007: EST.01.05), for example, make mention of *Chemical Engineering* magazine's Plant Cost Indices. These indices have been stable since 2000, indicating that labour prices have been more or less constant since 2000. In practice, however, this is not the case. Global engineering and construction firms have commanded increasing prices since 2003, particularly for large projects.

5.6 Some ideas in the development of an escalation tool

Hollmann and Dysert (2007: EST.01.6) offer the following steps in developing an escalation estimating tool:

- Get buy-in on the approach from the engineering and business communities.
- Decide on the cost account breakout to use for escalation estimates (preferably based on the standard code of accounts).
- Obtain the services of an economics firm that can provide the historical and forecast indices required.
- Obtain the up-to-date indices from the economist and develop weighted indices for each of the project's estimate cost accounts.
- Make adjustment to the weighted indices as needed, particularly for capital demand trends.
- Determine the estimated project cash flow by cost account.
- Apply the indices appropriately to the cash flow for each cost account.
- Decide how to handle escalation on contingency fund and escalation risk.

Cost estimators are, however, cautioned not to expect too much accuracy from cost indices (Lofton & Coppo, 2007: RISK.05.1). These indices are approximations intended to represent the average trends for a large group of projects in a broad region. The indices are generic and conceptual in nature and judgment must be applied in using them in any given situation. Escalation estimates should always be considered a Class 5 estimate. Refer to Chapter 3 of this study for estimate classification.

6.0 MANAGING ESCALATION

As mentioned previously, cost escalation in the construction market is a cumulative effect of a number of different factors (Abi-Karam, 2004a: DEV.04.2). While each of them may only contribute a small amount to the overall cost of a project, when combined they are a driving force behind the rising costs of constructing a new plant (Butts, 2007a: EST.08.1). Because there are so many factors contributing to escalation, managing escalation requires a variety of strategies.

The increases of hard prices are a reality. It is worth noting that over a ten year period, construction material escalation is broadly in line with the broader measures of escalation (Morris & Willson, 2006: CSC.06.1). It should also be realised that as long as construction volume remains high and the pool of skilled workers does not grow to accommodate the demand, bidders will always have options (O'Mahony *et al.,* 2008: 14380). Jansen-Rommijn (2008: EST.13.1) and Nassar and Hegab (2006: 556) point out that projects which are perceived as difficult, whether for the complexity of the design, the level of regulatory requirements, the location of the project, or even the reputation of the project owner, are less likely to attract bidders, and those who are willing to bid on these projects are more likely to increase their bids to cover their risk.

Noor *et al.,* (2006: OWN.05.2) state that the estimator should realise the volatility of bidding. Material prices will continue to fluctuate, although perhaps not to the extent seen in recent years (Morris & Willson, 2006: CSC.06.1). Bidder's interest will continue to fluctuate, based on the amount and type of work available at any given time.

Touran and Lopez (2006: 854) reveal that the dominant escalator in the current market is poor allocation of risk. Yiu and Tam (2006: 478) state that traditional bidding methods place the bulk of the risk on those who are least able to absorb any fluctuations in cost. To manage cost escalation and minimise the impact of future cost increases or other factors which will arise to put additional pressure on the market, project owners need to change how they think about, and handle projects (Hollmann & Dysert, 2008: EST.08.2). The party who will have to accept the risk involved in the project will charge a premium (Arrow, 2008: RISK.01.2). By passing the risk to the contractor, they will put premiums in their bids and by requiring contractors to submit hard money bids for long term projects, the risk is passed to the vendors who will also build a premium into their bids. Perhaps the best option for project owners to minimise

the impact of the volatile construction market is to become partners in the risk (Autiero, 2000: 52; Babusiaux & Pierru, 2009: 104).

The first step is for project owners to take more responsibility for the risk associated with material price fluctuations (Cicmil & Nicholson, 1998: 98). Because the owner is more diversified, he is better able to handle the risk. This can be done in a number of ways at each level of the design and construct process (Carbone & Tippett, 2004: 29). To help and absorb the risk for contractors, project owners can:

- Include fluctuation clauses (Cheng & Yang, 2001: 295) which will allow for shifts in material costs; in other words, the owner agrees to cover the cost of materials and does not require the contractor to submit a fixed price for something they may not be able to purchase for quite some time.
- Pre-purchase materials to limit the impact of future price fluctuations (Formoso, Soibelman, De Cesare & Isotto, 2002: 319).
- Provide dedicated float for slippage by understanding that, due to current market and transient material shortages, some scheduling delays may be inevitable (Nassar, Gunnarsson & Hegan, 2005: 1258).
- Reduce the bid award period to accommodate shorter price locks.
- Delay the bidding of non-essential packages so that when those items are bid, prices can be closer to actual costs at the time they are needed.
- Negotiate sub-contracts along with the contractor.
- Use Cost-Plus contracts (Rossetti & McKeeman, 2008: 7).

At all levels of the project, the key aspect for the project owner is to actively manage design and cost by ensuring that all participants in the design process are fully aware of budgetary constraints as well as the impact of any changes or delays on overall project cost (Morris & Willson, 2006: CSC.06.1). This will likely require a departure from the usual method of designing and constructing projects and takes committed leadership, freedom of action at project level, and most importantly, more work and commitment from all members of the project team to meet higher performance expectations (Singh, 2003: 316).

A challenge of escalation estimation, by any method, is the reliability or accuracy of the forecasts (Vargas, 2004: CSC.16.3). The first step will be to obtain indices from economists that correspond to the markets of interest, particularly local wage rates and

regional and global CAPEX for the subject industries (Yisa, Ndekugi & Ambrose, 1996: 52). The advantage of probabilistic methods is that even if the resulting forecast is inaccurate, management will have the opportunity to really understand the risks and make an informed decision on how to address that risk (Sorenson & Lavelle, 2008: 43).

As with all estimating, management tends to have unrealistic expectations of escalation estimate accuracy (Chen, O'Brien & Herbsma, 2005: 671). It can also be expected that the use of CAPEX indices to develop proxy factors will be challenged. This methodology has not been covered by extensive literature which might be the reason why proxy factors have not been a popular method.

7.0 ESCALATION VERSUS CONTINGENCY FUND

As stated previously, escalation is defined as underlying economics-driven changes in price levels. Escalation is not controlled and driven by any company's management (Hollmann & Dysert, 2007: EST.01.3). It is macro-economics driven (Akerlof, 2007: 16) and largely out of the control of the estimator. Project cost increases are normally the result of poor project practices of which escalation is but one factor (Devine, 2006: INT.06.2). Escalation in itself is not doubling or tripling project costs. Poor project practices are a well-known cost risk driver that should be addressed by the contingency fund, not escalation (Ford, 2002: 30; Sonmez, Ergin & Birgonul, 2007: 36).

Even the best defined and managed projects will face price increases driven by underlying economic conditions (Faig & Jerez, 2006: 4; Waara & Bröchner, 2006: 799). Poorly defined and poorly managed projects are, however, more likely to be affected by increased costs. These increases can be seen as contingency risk and not escalation. The contingency fund has a negative connotation, in the sense that management believe it to be "fat", and they are not receptive to the idea that their own poor practices is what is causing much of the cost growth (Whiteside, 2007: EST.04.1; Rothwell, 2005: EST.18.2).

Another principle to understand is that escalation is not costs that result from the manager's project scope and execution strategies (Robinson, 1996: 8). For example, if an owner selects a high price bidder just because he can deliver his equipment first to site, the difference in tender prices between this bidder and the second bidder cannot

be seen as escalation (Butts, 2007a: EST.08.1). Similarly, choosing to offer contractors incentives such as overtime and bonuses is an owner's management choice (Singh, 2003: 315). The portion of the price that is "contractor's risk premium" is affected by owner's choices. Specifically if the owner chooses to push all risks to the contractor by using fixed price contracting, then the higher prices are the result of the owner's choice, not escalation (Singh *et al.,* 2007: 22).

8.0 CONTINGENCY

Contingency project performance is frequently measured in cost, time, and the value of the constructed facility (Skitmore & Ng, 2002: 457). Blyth and Kaka (2006: 87) point out that a traditional approach to mapping multiple objectives applies a zero-sum-gain perspective in which the aggregate performance in these three dimensions is assumed to be fixed and trade-off decisions are used to achieve better performance in more important dimensions at the cost of poorer performance in less important dimensions.

Accepting increased cost to reduce project duration by paying for overtime is perhaps the most common application of a zero-sum-gain approach to managing construction projects (Ford, 2002: 30). This approach forces managers to choose among lower cost projects, shorter project duration, or better facilities and contrasts sharply with their desire to satisfy all three of these project objectives. Strategies are being sought that can simultaneously improve project performance in multiple dimensions (Ford, 2002: 30).

Project budgets are one of the most important and widely used project management tools (McDuling, Horak & Cloete, 2004: 2). Project complexity and the inherent uncertainty of the financial performance of constructed facilities, development funding, and the control of costs and schedules make exact budget needs impossible to forecast accurately. These same characteristics also cause projects to deviate from plans (Nepal, Park & Son, 2006: 185). Therefore, contingency funds are included in development budgets to provide managers with the flexibility required to address uncertainties and deviations that threaten achieving objectives (Nima, Abdul-Kadir, Jaafar & Alghulami, 2004: 316). The contingency fund is important in realising project objectives and can represent a large portion of the project budget (Noor & Tichacek, 2004: RISK.04.2). The effectiveness of contingency management can therefore have a strong influence on project success. Large contingency fund sizes, the challenges of managing a contingency fund, and the central role of budget contingency fund in

determining project success, make contingency management an important project management issue (Ford, 2002: 30).

Bonhomme-Delprato (2008: 13) demonstrates that contingency fund is defined as the amount to be added to the competitive base estimate, prepared realistically for the known scope assuming typical site/market conditions/oversights/unknows, and is free of excessive allowances and mark-ups, as per historical experience so that the final project cost estimate has an equal chance of falling above/below the actual cost or the initial quantifiable estimate (Prasad, 2008: EST.S02.1). Retief and Ker-Fox (2004: 1) suggest that the contingency fund is intended to mitigate the adverse impact of the unforeseen events. It is a reserve and hedge against risk for estimate assumptions. These risks can include budget estimates, activity durations and sequencing, resource requirement, historical benchmarking or database inputs being repetitive, resource availability, vendor co-operation, strikes, etc. The risk allowance is not for scope growth increase or interest rate changes. Ripley (2004: CSC.08.1) recommends a combination of factors to be considered when deciding on a contingency fund. They are design definition, estimating method, estimator's experience, time frame, schedule probability, new technology or proto-type engineering, remoteness of job site, engineering progress at the time of estimate, and material commitment at the time of estimate. It is not a function of changes in the defined scope of a project or the unforeseeable circumstances beyond management's control. Rather it is money that is expected to be spent, hence, controlled (Prasad, 2008: EST.S02.1). Figure 6.11 shows combined cash flow and contingency fund requirements.

8.1 Bid risk and contingency analysis

The exact amount to bid is a taxing decision for the contractor from the viewpoint of accuracy, primarily because of the inherent risks involved in projects and work packages (Carr, 2005: 1165). These risks, which vary from nearly every item that is a project expense, can range from being significant to insignificant, and result in either cost overruns or profit opportunity.

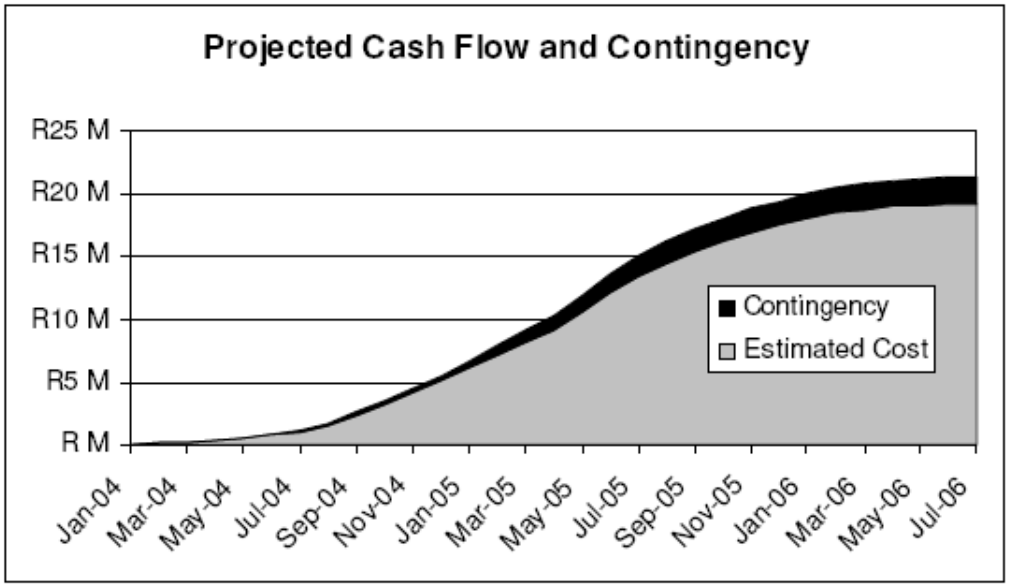

Figure 6.11: Combined cash flow and contingency requirements

Source: Retief and Ker-Fox, 2004: 4

Project expense items have a range of possible costs. These costs can be optimistic enough such that the contractor can afford to either bid low or bid normal and charge high profits or else can be pessimistic enough, such that the contractor is compelled to bid high and face lower profits (Berends, 2006: 37). However, before contractors decide on making an investment, they need to inevitably analyse the risks and profitability of the investment if they hope to submit a reliable estimate (Carr, 2005: 1165). If the risks and profitability do not fulfill the expectations of the contractor after analysis, the investment is not likely to be pursued (Lo, Lin & Yan, 2007: 410).

Nutakor (2007: 10) indicates that one of the most common methods of awarding construction projects is the lowest bidder system. It is a competitive system through which most vendors obtain their work with price being a predominant factor or sole criterion (Tebin, 2009: 8). While the awarding of contracts for construction work on the basis of competitive bids offers certain advantages to both owners and contractors, it is believed that many of the construction industry's problems can be traced back to making price the sole criterion (Kassab, Hipel & Hegazy, 2006: 1045). Furthermore, though the lowest bid may be attractive, it may not be the lowest final cost (Lo *et al.,* 2007: 410).

8.1.1 Data analysis procedures

Table 6.4 demonstrates the extent of possible factors that can influence the bid price and will ultimately have an influence on the level of contingency fund (Nutakor, 2007: 11). Nutakor (2007: 16) further determined that there are seven main contributors to cost overruns on projects in the oil and gas construction industry:

- change orders,
- level of scope definition,
- bid process,
- contract risk,
- market conditions,
- risk management issues, and
- performance.

The factors mentioned in Table 6.4 are more influential at the beginning of the project. As the project draws to a close, nearing plant commissioning (Bosch, 2004: 9) these factors will be less influential or will completely fall away (Noor *et al.,* 2006: OWN.05.2). Figure 6.12 illustrates this point.

Primary coding category	Secondary coding category
Change orders	- Number and magnitude of changes - Change order administration/management - Changes in work condition or situation - Variation in quantity
Level of scope definition	- Design or engineering completeness - Differences in opinion as to scope - Changes in scope of work - How well responsibilities are defined - Thoroughness of risk analysis on design - Inconsistent documentation (quality of bid package) - Right contractual terms
Bid process	- Time to bid - Clarity of request for bids - Mistakes in sub-contractor's bids - Omissions by bidder - Completeness of bid package - Thoroughness of pre-award interview - Bid clarification
	- Higher contract administration costs - Litigious nature of owner

Contract risks	- Litigious nature of sub-contractor - Litigious nature of designer/consultant
Market conditions	- Change in wage rates - Change in material prices - Quality and availability of work force
Risk management items	- Job location - Contractor's construction management expertise - Owner's construction management expertise - Risk allocation to the right party - Whether bidder has assessed the difficulty of the work correctly or not
Performance	- Rework (because of quality by contractor or sub-contractor) - Rework because of late changes by owner or designer - Failing to meet specifications due to interpretation differences - Owner's influence on contractor or sub-contractor (schedule effect) - Effect of site productivity - Field supervision costs

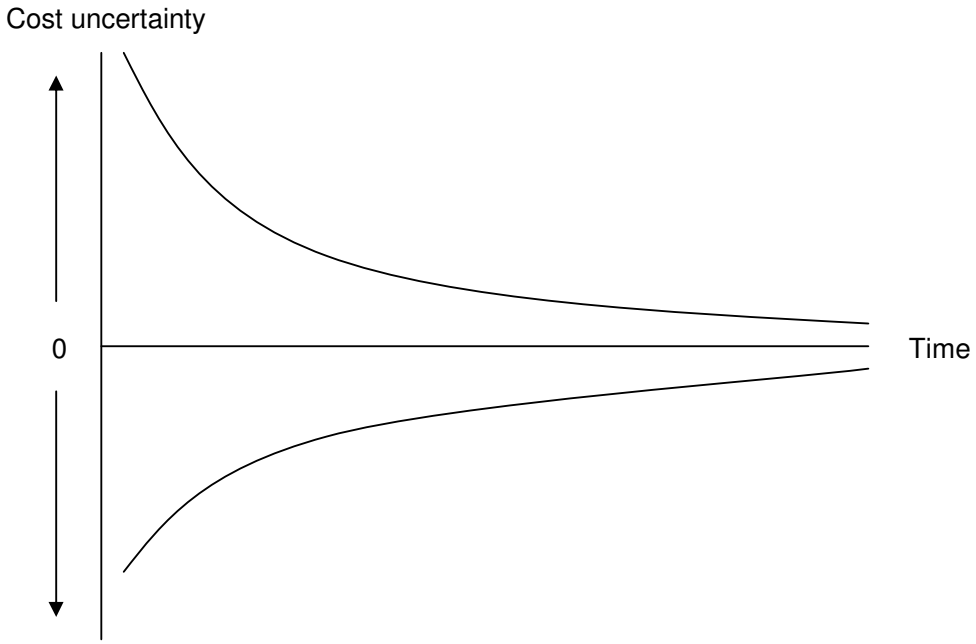

Figure 6.12: Variation of cost uncertainty with project execution/bid timeline

Source: Noor *et al.,* 2006: OWN.05.2

During the process of determining risks, two main tasks are accomplished. The first task is the identification of potential risks that may influence the base estimate. This list can be obtained from experiences on past projects (Lo *et al.,*2007: 411). Once the list of risks is compiled, the risks are grouped into categories as displayed in Table 6.4. If the bidding information is properly compiled, the client/contractor can displace much of the risk on the project to the bidder. These risks will be allowed for in the bidder's price/rates.

8.1.1.1 3 Point price estimates

It is customary on projects to obtain three estimates for all material, equipment, labour and sub-contractor items (Thomas & Ellis, 2007: 542). In addition, before probabilistic cost analysis is performed, there should be no doubt that the scope of work and specifications need to be adequately fulfilled. Estimators need to understand the methods involved in construction. Getting the three estimates ensures that ups and downs are covered and that the price is representative and reliable, enabling the contractor to make an informed decision on the final selection.

As the contractor receives more and more estimates for work packages, these estimates can be subdivided into three parts – a most likely range, a pessimistic range and an optimistic range (Thomas & Ellis, 2007: 543). For the amount of uncertainty and risk associated with costs, subdividing into additional ranges beyond the three above is unnecessary work that does not yield further information of much value. Considering three ranges is simplistic, accurate and representative.

8.1.1.2 Work packages

Construction projects usually have hundreds of thousands of work packages. Singh, Shiramizu and Gantam (2007: 20) demonstrate a technique of risk and contingency analysis by using only three work packages as an example. They refer to A, B and C, which are respectively foundations, civil works and structural works. Overhead costs, personnel costs and indirect costs can also form part of these work packages.

Various factors, such as variability in project activities, material and labour costs, will influence the probability of cost overrun or under run of the project (Ling, Chan, Chong & Ee, 2004: 76). Work packages costs can fluctuate for a large number of reasons, including slow worker production rate, lost work days because of sickness, injuries or

accidents, material shortages, delays in material arrival, faulty material, compressed schedules, rework due to poor quality, weather problems, crisis situations, misleading drawings, owner interference, terrain difficulties, poor estimating, lack of equipment performance, poor worker morale, etc.

Identifying and understanding risks is important to obtain a reliable estimate (Hannon, 2005: EST.09.2). However, risk analysis does not simply stop at identification and understanding of risks. The identification and understanding needs to be reverted to actual costs to get a solid grip on the budget ramifications of risk (Ling *et al.,* 2004: 77).

8.1.1.3 Price probability

Singh *et al.,* (2007: 20) expand on their work package example of A, B and C. Say, for example, that for work package "A" the contractor only gets three prices – $5, $7 and $10 (in thousands of dollars). The probability of obtaining a $5, $7 or $10 price on the project is therefore 33% each. If the contractor gets two quotes for $5, three quotes for $7, and one quote for $10, the probability of achieving $5 on the project is 33%, for $7, 50%, and for $10, 17%. Such a procedure for evaluating probabilities is valid when one has histograms to represent the frequency of prices.

8.1.1.4 Triangular distribution

One approximation that simplifies the analysis of the frequency distribution created above, as well as allows a continuous analysis, is the use of the triangular probability distribution as a surrogate for normal distribution (Singh *et al.,* 2007: 20). If one considers low, medium and high frequency levels, it is possible to obtain triangular distributions for commensurate optimistic, most likely and pessimistic prices.

For example, a triangular distribution could be as seen in Figure 6.13. A polyline could ensue such as in Figure 6.14 where an extreme price (the pessimistic price in this case) is expected to occur with some medium level of frequency. Fundamentally, the triangular shape is the expected distribution profile for data within the range of prices.

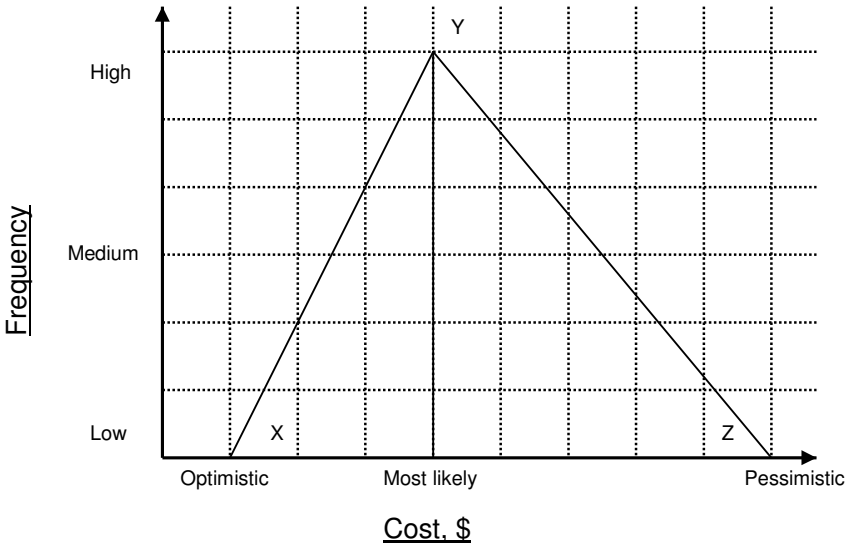

Figure 6.13: Triangular distribution of costs

Source: Singh *et al.,* 2007: 23

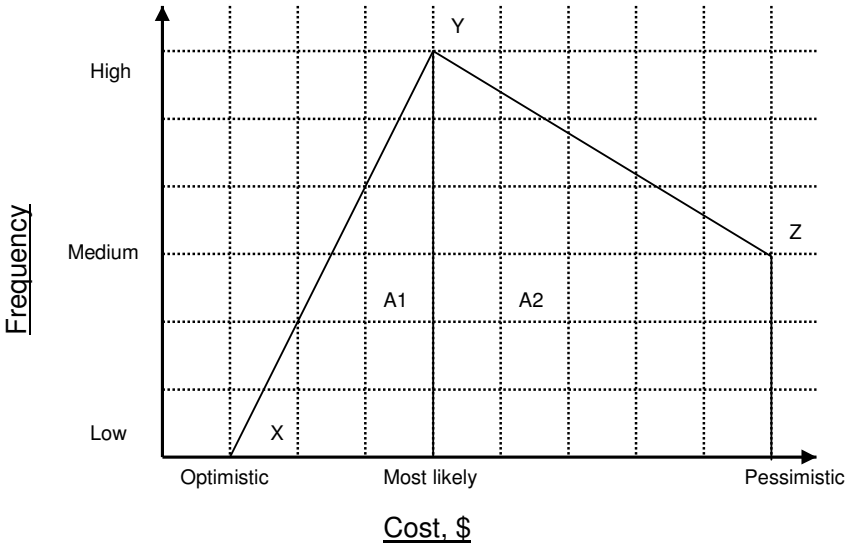

Figure 6.14: Polygonal distribution of costs

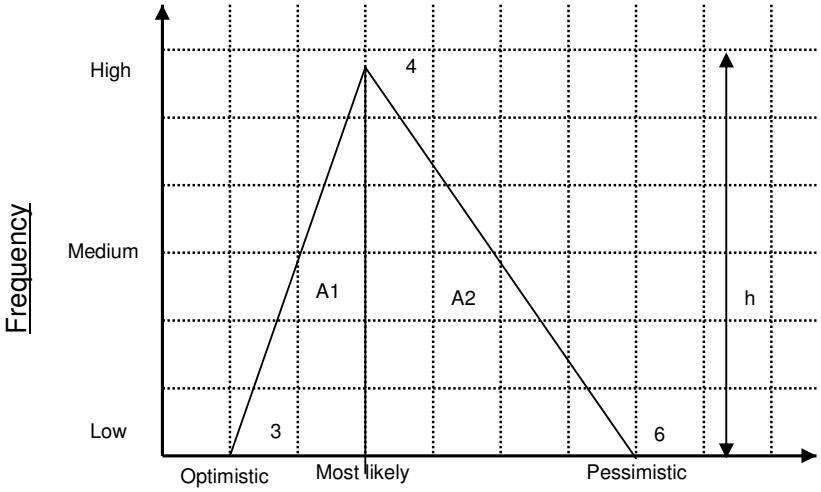
Source: Singh *et al.,* 2007: 23

8.1.2 Obtaining prices

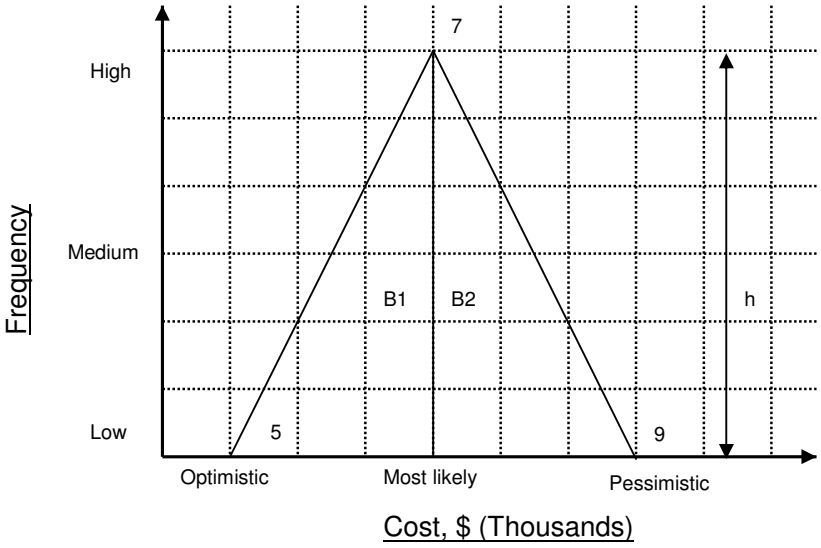
Depending on how the pricing is being done, it is not necessary to obtain market prices for any particular work item if the estimator has enough experience. Combined with some feel for the under run or overrun, he can assign appropriate frequencies to the prices and arrive at a triangular or polyline distribution (Williams, 2006: 40). Thus the estimator can determine the absolute minimum price of a project as well as the

absolute maximum cost of as project, with potential prices ranging in between those extremes.



Estimators have different ways of determining prices. Whether the rates are based on market prices, or on historical data, or calculated from first principles – the bottom line is that the prices must be divided into three categories: optimistic, most likely, and pessimistic (Yiu & Tam, 2006: 476).

8.1.2.1 Frequency approximation by triangular distribution



Triangular distribution uses graphing, calculating triangular areas under the "curve" and probabilities in order to organise contractors' bids. The basic assumption required for using triangular distribution is that the area under the "curve" represents the probability of cost. Each work package contains different elements of the project. A computer with specific software is recommended when this exercise has to be done on a real project, but for discussion purposes the following example can be used.

Singh *et al.,* (2007: 23) point out that if there are three different ranges of bid prices for a project consisting of three work packages (WP), namely work packages A, B and C, after the basic data has been collected and organised, each work package needs to be analysed individually. Figure 6.15 illustrates the triangular distributions for the three work packages. The areas under the graph represent the infinite number of possibilities that exist for specific work package prices occurring at a specific frequency. If an infinite number of bids can be obtained, the distribution plot can be approximated to the triangular distribution graph of Figure 6.15.

Work Package A

Work Package B

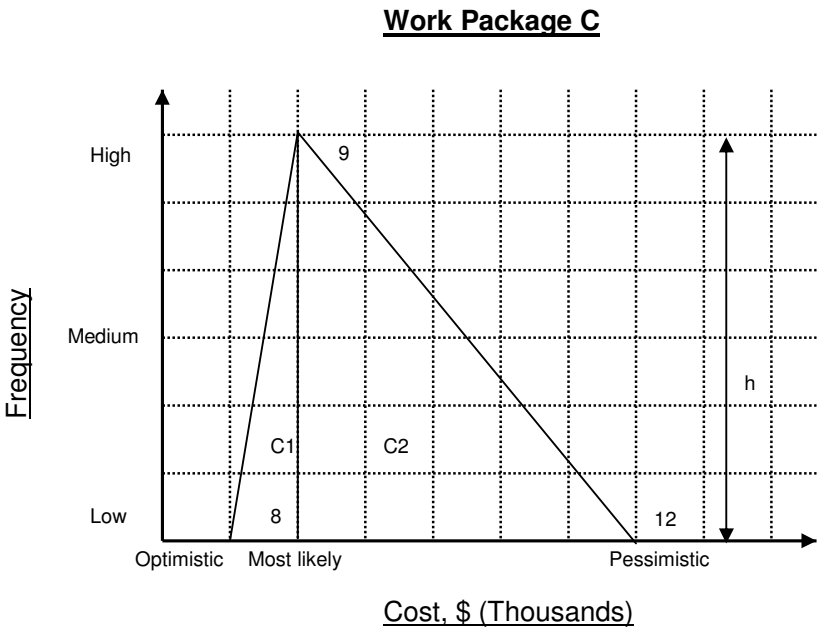


Figure 6.15: Triangular distribution costs of three work packages A, B and C
Source: Singh *et al.,* 2007: 22

To determine the probability of occurrence of any range of any work package, one must find the area under the curves. The areas of the respective triangles under each range must be calculated. The total area under the graph represents 100% probability of occurrence. Thus for work package A:

Area of Triangle A1 = ½ x 1 x h = 05.h

Area of WP Triangle A2 = ½ x 2 x h = h

Total area of work package A = Area of A1 + Area of A2 = 0.5h + h = 1.5h

Where h is the height of the most likely frequency, the areas for other WP ranges are found similarly. These are presented in Table 6.5.

Triangle	Area	Probability of Occurrence (P)
A1	0.5 x (4 - 3) x h = 0.5h	A1 / (A1 + A2) = 0.5h / 1.5h = 0.33
A2	0.5 x (6 - 4) x h = 1.0h	A2 / (A1 + A2) = 1.0h / 1.5h = 0.67

B1	0.5 x (7 - 5) x h = 1.0h	B1 / (B1 + B2) = 1.0h / 2.0h = 0.50
B2	0.5 x (9 - 7) x h = 1.0h	B2 / (B1 + B2) = 1.0h / 2.0h = 0.50
C1	0.5 x (9 - 8) x h = 0.5h	C1 / (C1 + C2) = 0.5h / 2.0h = 0.25
C2	0.5 x (12 - 9) x h = 1.5h	C2 / (C1 + C2) = 1.5h / 2.0h = 0.75

Table 6.5: Probability of occurrence
Source: Singh *et al.,* 2007: 24

Subsequently, the probability of occurrence of the zone represented by A1 is:

Prob. (A1) = Area of A1 / Total area of WP A = 0.5h / 1.5h = 0.33

Similarly, the probability of occurrence of the zone represented by A2 is:

Prob. (A2) = Area of A2 / Total area of WP A = h / 1.5h = 0.67

To obtain the probability of the overall costs on the project and to determine the final bid price, the individual probabilities of occurrence for the triangles in Table 6.5 need to be combined. The target cost is defined as the sum of the most likely costs for each work package. Figure 6.16 indicates a confidence of 29% at a value of $20K. The contractor might not feel comfortable to bid his work package with this price if he has a 70% chance of an overrun. This seems to be a risk situation where only the contractor can make a decision. A reasonable decision involves ascertaining the confidence limit with which the contractor feels satisfied.

Assume the contractor feels safe with either a target price or 80% confidence. Figure 6.16 indicates that the 80% confidence level represents a price of $22.10K, which is higher than the target cost. Should the contractor choose this value, he will be able to meet the target price and will be able to set aside a contingency fund.

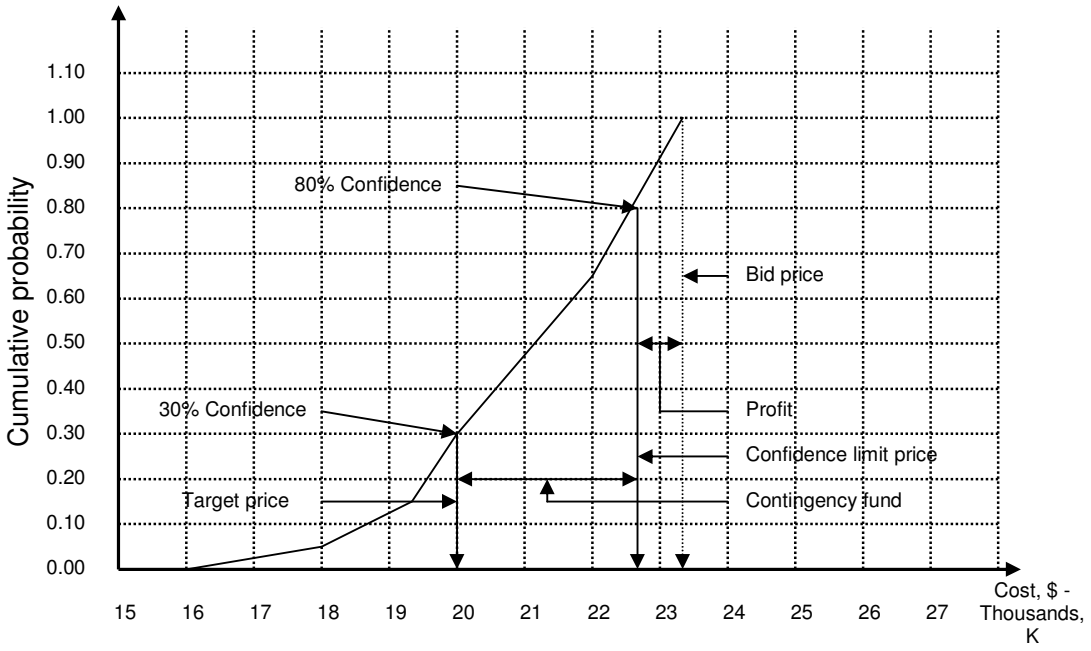

Figure 6.16: Confidence limits, bid price, and profit and the project

Source: Singh et al., 2007: 23

8.1.3 Beyond-contractual reward (BCR)

In the competitive bidding system, price is the decisive criterion so contractors may win the bid by tendering an abnormally low bid, accidentally or deliberately (Lo *et al.,* 2007: 409). When contractors begin construction under an unfavourable condition in terms of price, they often adopt some strategies to compensate for the deficit, such as using inferior material/labour and bringing up claims against the employer (Oyegoke, 2006: 98). All compensations gained beyond the contract are called beyond-contractual reward (BCR).

In general, contractors tender an abnormally low bid due to insufficient professionalism or cursory calculations. Such situations are referred to as “winner’s curse”, by which the contractor who wins the bid undertakes the construction at a sacrifice (Lo *et al.,* 2007: 410). The main factor that might cause serious problems for the construction market is contractors’ deliberate low-bidding behaviour. Certain bidders will extensively review the bidding documents, noting mistakes and ambiguities that will lead to loopholes in the contract and will pave the way for future in-contract claims. These bidders can lower their bid prices with the knowledge that they will be able to recover any “losses” in future change orders/claims (Yiu & Tam, 2006: 478).

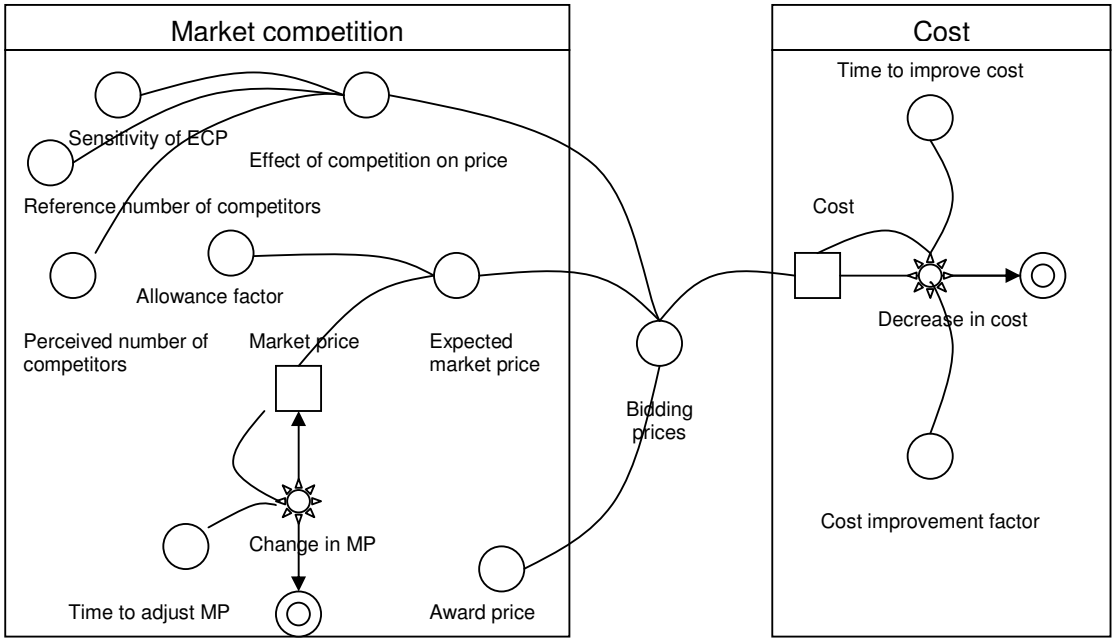

Figure 6.17: Contractor's pricing without consideration of BCR

Source: Lo, Lin and Yan, 2007: 411

Figure 6.17 indicates that a contractor's bidding price is influenced by interdependent variables from two dimensions of cost and market competition. According to the aforementioned assumptions, historical award prices and the number of competitors are the two fundamental considerations in the dimensions of market competition (Struts & Griffis, 2005a: 623).

8.2 Contingency fund calculation

Retief and Ker-Fox (2004: 1) indicate that contingency funds are widely accepted budgeting tools for affording projects acceptable levels of cost reliability. However, a global contingency pool can be misleading early in the project. Risk associated with initial project definition can consume a disproportionate amount of contingency, exhausting the available reserve funding prior to project completion.

Prasad (2008: EST.S02.1) points out that the concepts of contingency formulation is based primarily on the contract type being fixed fee (lump sum) or cost-plus (where a normal contingency fund is applied as required for budget restraints, engineering, etc.). Contingency setting remains one of the key areas of concern for a company's project system as the assignment of reliable contingency allowances in project cost estimates can make or break a project (Burroughs & Juntima, 2004: EST.03.1).

Over the years various contingency setting techniques have been developed in an ongoing search for reliable approaches. These techniques vary from simple to complex in their development and use, but all have the objective of improving the accuracy of the project estimate.

Burroughs and Juntima (2004: EST.03.1) describe contingency as an amount of money that experience has demonstrated must be added to the base estimate to provide for uncertainties related to (a) project definition and (b) technological uncertainty. Contingency is money that is expected to be spent. The contingency account is not to provide for changes in the defined scope of a project, or for unforeseeable circumstances beyond management's control. Contingency should also not be viewed as a reserve or slush fund that the project team cannot spend without upper management's approval. Likewise, management should not have the expectation that if a project team does its job well contingency will not be spent. Burroughs and Juntima (2004: EST.03.1) comment on an approach of setting a contingency at an amount that achieves a 50% probability of overrun. At a 50% probability the project system, on average, is expected to spend its entire contingency.

The previous discussion assumes that the base estimate is a realistic and competitive estimate of the known scope and also assumes typical site and market conditions. A competitive base estimate is free of excessive allowances and markups for general unknowns. Allowances to cover specific, but uncertain items are within the base estimate. The competitiveness of the base estimate is a key factor to consider in contingency setting (Burroughs & Juntima, 2004: EST.03.1).

The majority of projects set their contingency using techniques that can be grouped into one of three categories: predetermined percentage, expert's judgment, and risk analysis.

8.2.1 Predetermined percentage

Burroughs and Juntima (2004: EST.03.1) point out that most companies using this form of contingency setting would allow 5 to 10% of their base estimate as a contingency. This form of allowance may seem arbitrary, but this allowance is a reasonable average for contingency use in the process industry.

The advantage of this method is its ease of use and its consistency. Using a consistent percentage removes subjectivity from the process. Because of its ease of implementation, a fixed contingency percentage is often the technique applied to smaller projects. The disadvantage of the method is that it removes specificity and subjectivity from the process; it is inflexible to potentially important risk drivers, such as process complexity, use of new technology, and level of project definition. Because of this, this method tends to under-estimate contingency needs for complex or poorly defined projects and to over-estimate for simple or well-defined projects. By failing to take project risk drivers into account, the pre-determined percentage method produces large variations in the probability of overrun or under run from project to project.

8.2.2 Expert's judgment

A more advanced and flexible methodology for determining contingency is to use educated judgment of experts to assist in setting a contingency level (Unal *et al.,* 2005: 34). In this technique, skilled estimators and project team members use their experience and expertise to assign a level of contingency that they believe is appropriate for the project at hand. Unlike the pre-determined percentage method, expert judgment considers specific risk factors and base estimate competitiveness.

The degree of structure to this form of contingency setting process varies widely. Typically, the experts must consider bounds or norms (formal or informal) for contingency outcomes. These bounds may be expressed by using an expanded version of the pre-determined contingency approach whereby the experts must select from contingency that are pre-determined for discrete risk levels. If the process is more highly structured than this, it tends to be classified as a risk analysis (Humphreys, 2004: 3).

By using specificity and subjectivity in setting each project's contingency level, a project system is more likely to have more accurate estimates (Kasprowicz, 2004: 2). However, subjectivity is also the main disadvantage of this method in that the skill, knowledge and motivation of the experts may vary widely. Typically, only a few experts are available whose understanding of project cost risk and estimate competitiveness can be relied on. This experience is not easily transferable, which makes turnovers a primary concern (Al-Tabtabai *et al*., 1997: 283).

8.2.3 Risk analysis

Risk analysis techniques examine risk factors in a more structured way than expert judgment and apply specific quantitative methods of translating the assessed risk into contingency values (Humphreys, 2004: 2). The quantitative methods are usually probabilistic and allow the statistical confidence level of cost outcomes to be considered (Touran, 2003: 281).

The most commonly used form of risk analysis employs Monte Carlo analysis as the quantitative method. In this technique, a probability distribution is assigned to each estimate line item or subtotal, and the simulation tool randomly selects a possible outcome from each item's distribution and aggregates the item outcomes into a total expected project cost outcome (Vrijland, 2005: DEV.06.1). This process is repeated many times to obtain an average total cost. The distribution of the iterative outcomes can then be used to select a contingency value that provides the level of statistical confidence desired (Whiteside, 2008: EST.04.2).

The main advantage of risk analysis techniques is that they are probabilistic in nature. They allow confidence levels to be explicitly considered and they are flexible (Hollmann, 2007a: RISK.03.6). Monte Carlo analysis can be applied to any estimate or cost analysis that can be totalled or modelled in a spread sheet.

Koller (2005: 3) states that risk analysis techniques have another advantage if the risk assessment step is done in a group setting wherein the project team reviews the entire estimate from a risk perspective. This is often the only review of the estimate, and the outcome of the review is almost always an improved base estimate, as well as a probabilistic contingency value.

Kubitscheck (2000: 40) proved that a disadvantage of risk analysis techniques as typically applied can be that the estimate items for which probable outcome distributions are being assigned are not, in themselves, risk drivers. The distributions assigned, therefore, tend to be somewhat meaningless. For example, the typical cost model is a spread sheet tabulation of estimate elements such as piping and electrical line items. Lapinski, Horman and Riley (2006: 1086) mention that the estimator is expected to assign a probability distribution to "piping". However, if the major risk driver is the level of project definition, few estimators will have a really good idea of how project definition will affect any particular line item (Kraus, 2008: 3).

Risk analysis also requires more time and resources to implement when compared to predetermined percentages or expert's judgment (Lavingia, 2004: PM.09.1). The Monte Carlo technique is also deceptively complex (Lin & Shen, 2007: 6). For example, it requires that dependencies be established between elements of the cost model. The complexity also allows outcomes to be easily manipulated, thus the results are often inconsistent. The time and complexity of risk analysis techniques often mean that they are reserved primarily for larger projects or projects of increased business importance (Garlick, 2007: 3).

8.3 Significance of work breakdown structure in contingency modelling

Zhao (2006: RISK.05.2) suggests an improved contingency management tool by breaking the contingency allowance down into the work breakdown structure (WBS) of the project. In the qualitative risk assessment process, the risk breakdown structure (RBS) offers "a source orientated grouping of project risks that organises and defines the total risk exposure of the project" in a hierarchical structure.

Each WBS account bears different types and degrees of risks, therefore the variability of uncertainty can be a wide swing between accounts (Verveniotis, 2008: PM.02.2). An unbalanced WBS could skew the simulation results because the variations of risks could be generalised instead of specific. Zhao (2006: RISK.05.3) states that the main advantages of WBS usage to help break down the estimate are the following:

- Future changes can be attributed to the associated WBS accounts.
- Human errors can be traceable back to appropriate WBS home domains.
- Responsible individuals can be accountable for respective WBS contingency.
- Potential savings can be recognisable in corresponding risk-free WBS.

The whole process of modelling risks goes to the heart of cost management (Singh, Oh, Labi & Sinha, 2007: 220); Cullen, 2004: CSC.01.1). Appropriate allocation of the contingency funds to risk-affected WBS accounts also increases the project manager's accountability following the risk allocation principle (Groth & Kinney, 1994: 55). Furthermore, the contingency, derived from the simulation process, must be properly scaled and dispersed into WBS accounts following the approved project execution schedule. Hamilton (2004: CSC.12.3) points out that this dispensation of contingency

funds over time is referred to as a contingency drawdown management plan. All contingency budgets should be tied to specific risks (Guizhi, 2004: 3). The advantage of locking contingency into WBS based risk accounts not only provides project managers with certain flexibilities in managing their cost forecasts, but also prevents borrowing contingency money from other accounts or advancing from future timeline (Zhao, 2006: RISK.05.5).

8.4 Contingency misuse

According to Noor and Tichacek (2004. RISK.04.1), estimates are conducted with certain assumptions in mind - resources will be available, vendors will co-operate, there will be no strikes and inclement weather, etc. These assumptions can all lead to risks. The allowance for such risk is being dealt with by means of a compensation for these risks (Lenard, 2004: 2). This funding is referred to as “contingency”. Portions of the overall contingency are assigned against specific project activities or work packages.

Allowances for specific items or “known committed costs” differ from contingency in the sense that they are not risk based or dependent. Allowances are derived from elements that are expected to occur, and are within the scope of the project. Should the contingency not be utilised for the assigned activities it can lead to the misuse of the contingency allowance that might result in cost overruns on the project.

8.5 Contingency management

Construction project performance is frequently measured in cost, time, and value of the constructed facility (Ford, 2002: 30). A traditional approach to managing multiple objectives applies a zero-sum-gain perspective. The aggregate performance in the three dimensions (lower cost, shorter project duration, and better facilities) is assumed to be fixed. Trade-off decisions are used to achieve better performance in more important dimensions at the cost of poorer performance in more important dimensions (Oyegoke, 2004: 2). Accepting increased costs to reduce project durations by paying for overtime is perhaps the most common application of a zero-sum-gain approach to managing construction projects (Tichacek, 2005: CSC.11.2). This perspective forces managers to choose amongst lower cost projects, shorter project durations, or better facilities and contrasts with their desire to satisfy all three of these project objectives (Barraza & Bueno, 2007: 140).

Project budgets are one of the most important and widely used project management tools (Verster, 2004: 5). Project complexity and the inherent uncertainty of the financial performance of constructed facilities, development funding, and the control of costs and schedules make exact budget needs impossible to forecast accurately. These same characteristics also cause projects to deviate from plan (Barraza & Bueno, 2007: 141). Therefore, contingency funds are included in development budgets to provide managers with the flexibility required to address uncertainties and deviations that threaten achieving objectives (Evensmo & Karlsen, 2006: EVM.06.1). Large contingency sizes, the challenges of managing contingency, and the central role of budget contingency in determining project success make contingency management an important project management issue (Ford, 2002: 30).

Improving contingency management requires an understanding of how managers make budget contingency decisions and the impact of those decisions on performance (Kadir, Lee, Jaafar, Sapuan & Ali, 2006: 415). Several questions must be answered to model and understand contingency management. What cost, time and value objectives do managers seek to achieve with budget estimates?

Few formal theories of project budgeting and cost control are available. Kohl and Wulke (2004: IT.03.1) state that cost estimating tools facilitate developing budgets but do not address the management of budgets for contingency during projects. Most of the accounting systems record and report historical costs but do not facilitate management by forecasting monetary requirements or directly influencing future performance (Barraza & Bueno, 2007: 141).

The primary role of contingency is to counterbalance the risk of spending beyond the project's monetary resources due to deviations from project plans. Ford (2002: 32) identifies four contingency management objectives:

- Resolve emergencies: Protect against spending more than the budget by providing funds for future required unforeseen expenses.
- Control the schedule: Assure completion by the project deadline by accelerating progress.
- Improve the facility: Add value to the constructed facility, typically by design and scope changes or by adding to marketing or leasing programmes beyond minimum project requirements.

- Return excess contingency: Return contingency that remains after project is completed.

The first two objectives identify many of the risks identified in the literature that contingency are used to manage. Objective three directly impacts on the constructed facility and reflects the traditional project management performance measures of cost to deliver the facility (Mattheys, 2004: 5). In contrast, the fourth objective of contingency management is related to managerial performance but not directly to project performance.

Ford (2002: 32) mentions that exhausting contingency funds before the project is complete is considered a serious and grave condition. The speed at which managers are willing to reallocate funds to lower priority uses, and thereby increase the risk of exhausting contingency funds, distinguishes contingency management strategies (Atkin, Akintoye & Skitmore, 1993: 13). Consistent with the priority of the accounts, management efforts early in the project focus on reducing uncertainty by discovering the unexpected problems on the project and protecting their ability to meet project objectives by preserving contingency funds (Berends & Dhillon, 2004: 329).

Managers respond to decreasing uncertainty as projects progress by decreasing the funds considered necessary to address future emergencies (Kharbanda, Stallworthy & Williams, 1987: 87). As uncertainty decreases and deadlines approach, a majority of managers shift from primarily protecting contingency for later use to a willingness to use contingency to assure the timely completion of the project (Burroughs & Juntima, 2004: EST.03.1). Therefore, funds held to address emergencies decrease but total contingency spending increases as projects approach their deadlines. This increases the risk of exhausting contingency fund, because the contingency fund remaining is shrinking while the rate of contingency use is increasing.

Contingency management strategies are either aggressive or passive (Retief & Ker-Fox, 2004: 1). An aggressive strategy re-allocates funds quickly, uses contingency funds to correct schedules before many emergencies have been discovered and resolved, and applies funds early to improve the facility. In contrast, passive strategy re-allocates slower, postpones using contingency funds until it must be used to meet critical objectives, and uses little funds for improvement until emergency and schedule objectives are met.

Rowe (2005: CSC.14.1) demonstrates in Figure 6.18 the downward sloping channel that represents total project contingency over the construction period of the project. Typically, the baseline project budget is set at some point in the project life cycle (Alexopoulos, Mourtzis, Papakostas & Chryssolouris, 2007: 1688) and project managers must live within that contingency budget. Ideally, the baseline budget should not be set until the project manager has a good handle on the remaining project risk and can determine a sufficient value of contingency to include in the budget to cover that risk (Fang *et al.,* 2004: 855).

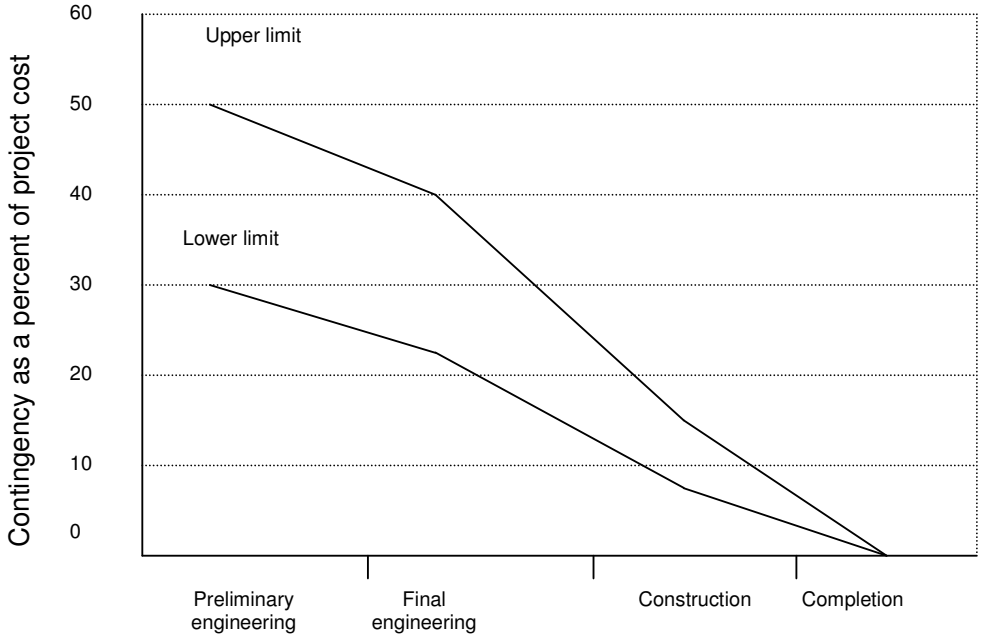

Figure 6.18: Project contingency should decrease over the construction period
Source: Rowe, 2005: CSC.14.2

During the construction phase, the estimate at completion of the contract packages changes more quickly than at any other phase of the project (Nutakor, 2007: 13). Potential contingency shortfalls need to be addressed to either re-deploy contingency, or to re-build the contingency allowance. By the start of the construction phase, final design should be complete and most, if not all, risk associated with each contract should result from change order growth occurring after contract award (Hanna, Camlic, Peterson & Nordheim, 2002: 59; Molly, 2007: 12). Since the estimate for a construction project is only intended to predict the bid price of the contract (Burrows, Pegg & Martin, 2005: PS.14.3), contingency fund must be included in the contract budget to account for change order growth.

Guidelines should be established to govern the amount of change order contingency to be assigned to each contract (Clare, 2008: EST.02.2). A survey of past experience with change order growth on completed contracts can provide a good basis for setting these guidelines. Doyle, Molnar and Brown (2008: OWN.02.2) state that typically, since different types of contracts contain different levels of change order risk, initial contingency guidelines should take the contract type into account. Table 6.6 shows an example set of guidelines by contract type.

Contract type	Initial change order contingency (as a % of contract cost)
Procurement only	5%
Typical construction	10%
Special construction:	
Tunnels	15%
Very small contracts	20%

Table 6.6: Guidelines for initial contingency assignment – example
Source: Rowe, 2005: CSC.14.2

Once construction contracts have been awarded, accurate forecasts are needed to track contingency consumption. The forecast should include the original contract price, the approved change orders, pending change orders, and all other identified cost issues. The cost of quality can be noted here (Abdul-Rahman, 1997: 465; Abdul-Rahman, Kwan & Woods, 1999: 594) as well as the indirect effect of construction delays (Abdul-Rahman, Berawi, Berawi, Mohamed and Yahya, 2006: 128; Aibino and Odeyinke, 2006: 667). A well-maintained forecast will change from day to day as issues are identified, negotiations are completed, and costs are agreed upon. It will, however, be impossible to accurately forecast the end-of-job cost just by allowing the known changes (Cheung, Yiu & Yeung, 2006: 807; El-Adaway & Ezeldin, 2007: 365). There will always be a certain amount of unknowns/risk items that will have to be catered for in the contingency allowance. The tracking of the contingency fund is another managerial function.

For simplicity, one could assign retained contingency funds based on the assumption that risk drops linearly as a contract is completed and is inversely related to the percent complete. As an example, at 80% complete, 20% of initial contingency fund

would be retained to account for changes that have not yet been identified. For each monthly forecast (F) reading, the Value of Changes Forecast (Δ_t) at the time was calculated by subtracting the Original Contract Amount (C_0) (Rowe, 2005: CSC.14.2).

$\Delta_t = F - C_0$

Once each contract is complete, the Final Contract Amount (CF) is known and the Final Value of Changes (Δ_F) can be calculated as follows:

$\Delta_F = C_F - C_0$

Rowe (2005: CSC.14.4) indicates that should a graph be drawn based on the actual data of historical projects, it will not follow a straight line, but will curve and taper off towards the end. Typical historical data for such a graph can be seen in Table 6.7.

Ripley (2004: CSC.08.1) notes the difference between “estimating contingency fund” and “management reserve”. The term “contingency” has been previously defined in this chapter and can be utilised for the following:

- Quantitative growth over and above the base quantities including the allowances in the Bills of Quantities (Diano & Cao, 2004: 2). These are associated with design development.
- Material costs – these are associated with quantitative growth, commodity pricing, shop loadings, equipment pricing, and other factors that impact on material cost (Menches & Hanna, 2006: 1286).
- Mechanical equipment and costs – these would be impacted by the timings of freezing the equipment list (Hanna, Camlic, Peterson & Lee, 2004: 765).
- Craft labour costs – these are associated with craft labour performance, quantitative growth, labour environments, craft availability, and other elements (Squires, Reid & Jeon, 2008: 85).
- Other factors that might be considered include items such as indirect field costs, home office labour, errors and omissions, schedule slippage, etc. (Simon & Sohal, 1995: 14 – 16).

Contingency management is an ongoing process, and a contingency management plan should be implemented early on (Barraza & Bueno, 2007: 143). This plan should

address how often the contingency fund will be re-evaluated, how the contingency fund draw downs will be handled in the intervening period, techniques to be utilised, and other issues. A periodical re-evaluation of the contingency fund should be the key feature of the process.

Percent complete (P)	Percent of final changes included in contract forecast
10%	8%
20%	36%
30%	52%
40%	63%
50%	72%
60%	80%
70%	86%
80%	91%
90%	96%
100%	100%

Table 6.7: Value of the ratio between Value of Changes Forecast and Final Value of Changes

Source: Rowe, 2005: CSC.14.4

Ripley (2004: CSC.08.3) recommends that the contingency fund be distributed across the contingent accounts in line with the risk assessment used to set the level of contingency fund. He also refers to the use of a draw down curve that relates contingency to the amount of activity completed. A similar approach using milestones could be used for the management of allowances.

The management reserve can be described as an amount added to an estimate to allow for discretionary management purposes outside of the defined scope of the project as otherwise estimated, in other words, for additional scope over and above the estimated scope. The management reserve is not expected to be spent unless management so directs, and is generally not included in all estimates (Ford, 2002: 38).

9.0 SUMMARY

Quantifying the risks associated with an estimate or cost forecast is one of the tasks which carries the most uncertainty and which can result in a substantial portion of the total construction cost. Mitigating this risk is a task that will necessitate a sound knowledge of risk analysis and risk management. Risk should be identified early in the project to cater for uncertainty, probability and consequences; allowing sufficient fund allocations on each specific risk.

The quantification of risk is done through risk analysis. Estimates are developed throughout the stages of the project. There are normally not a lot of project information available during the early stages of a project.. With incomplete information comes risk and it is this risk that is being addressed in the contingency fund.

Contingency funds are included in development budgets to provide managers with the flexibility required to address uncertainties and deviations that threaten achieving objectives. The amount of contingency that should be allowed is dependent on the level of scope definition, etc. Contingency management requires an understanding of how managers make budget contingency decisions and the impact of those decisions on performance. A popular method to perform contingency analysis is by means of a Monte Carlo analysis.

Monte Carlo analysis is normally used to allow for combinations of distributions. This technique is generally used to solve problems for which the definition of specific solution equations to calculate a specific answer is either too complex or too cumbersome to be practical. The use of Monte Carlo analysis can also be applied to escalation analysis.

Escalation comes from the interplay of changes, real or anticipated, in input costs, perceptions of risk, and perceptions of the competition. More often than not, it comes from the formation of market opinions, which may or may not have a basis of fact. Ultimately, the ability for contractors to raise prices depends entirely on the market conditions and the expectation that all bidders are increasing their prices. Increased input pricing and increased risk can influence that expectation, but cannot on its own increase prices.

As mentioned, price escalation and the contingency fund can amount to a substantial portion of the total cost of the project. The importance of the financial forecast lies in the fact that should fairly accurate data be available at the beginning of the project, management will be able to steer clear of possible pitfalls in unprofitable projects and improve their financial planning. A forecast is only correct if the base assumptions continue to exist in the future, however, most people treat the forecasts as nearly factual without updating the basis.

The following chapter deals with the development of a cost forecasting model. The combination of cost estimating and financial forecasting assists management in making purposeful decisions, and to consider important financial management decisions.

CHAPTER 7

LITERATURE REVIEW ON FINANCIAL FORECASTING MODELS

1.0 INTRODUCTION

Modern construction budgets are getting tighter, and owners and clients are demanding and expecting more from the contractor (Bredehoeft, 2004: EST.06.1). The importance of financial planning and forecasting cannot be overstressed. Several examples of international projects that cannot be considered financial successes are available. Broad (1990: The New York Times – June, 10), for instance, commented on the United States of America's Freedom Space Station. The initial budget for this project was $8 billion. The estimated final cost in 1990 was $120 billion and counting.

The management of a corporation needs to make financial decisions based on the forecasted profit that the business will accumulate on the projects it is currently busy with (Brooks & Coleman, 2003: 32). These decisions are deciding to the business' future and cannot be stalled until the project is completed. Most engineering projects run over a couple of years, so methods should be derived to properly report all costs on the project as well as to forecast possible future costs on the project (Carson, 2007: PS.02.1).

Chan, Scott and Chan (2004: 153) mention that there will most likely be time constraints in obtaining an estimate for scope changes. In most cases (especially in a design-and-construct environment) several designs will have to be tested and cost to obtain an optimum design (Cheng & Li, 2006: 831). This, together with constant additions and omissions to the current scope will make it almost impossible for the estimator to price, if he does not have a special set of skills and tools. These tools come in the form of Ratio Conceptual Estimating (RCE) which can be employed quickly and effectively (Chung & Skibniewski, 2007: IT.S07.1).

It is therefore important to understand the importance of the time and the influence it will have on costs should the project be delayed. Time also plays an important role in setting the financial forecast in the sense that the earlier the project team is made aware of substantial financial increases or decreases in the estimate final cost, the better this situation can be managed (Love *et al*., 2005: 187).

Project planning is therefore crucial in the success of the project. Several project scheduling techniques have been developed over the years (Verveniotis, 2008: PM.02.2). The project plan is developed in accordance with the phases of a project and in similar manner as project costs. These schedules should tie into the budgets and should be constantly updated through the life of the project to be able to apply proper cost control (Hyari & El-Rayes, 2006: 11).

As part of the cost control that will be necessary to manage the project at a financial level, it will also be necessary to create and update a cash flow model for each project (Louw, 2002: 218). Park *et al*., (2005: 172) states that a good cash flow technique needs to include both a historical trend-based data method and competent judgments based on construction experience. The availability to have access to cash is considered by some a luxury and should be obtained as far as possible (Odeyinka *et al*., 2008: 6).

Probably the most important aspect of cash flow analysis is the ability to forecast the projected final cost of a project to enable the project team to resource the project accordingly. The forecast of the estimated final cost begins during the pre-tender period (Skitmore & Drew, 2003: 36). The pre-tender forecast is updated during the construction phase of the project as new and improved scope detail surfaces.

A valuable tool when conducting financial forecasts is Ratio Conceptual Estimating (RCE). The basic methodology of this form of estimating has been discussed earlier in this study. By applying the historical database (Addendum D) one can perform quick and fairly accurate estimates of additions and omissions to the scope of work.

2.0 FINANCIAL FORECASTING

2.1 The value of time

Time is part of the measuring system used to sequence events, to compare the durations of events and the intervals between them, and to quantify the motions of objects (Duff, Okun & Veneziano, March 2002). Time has been a major subject of religion, philosophy and science, but defining it in a non-controversial manner applicable to all fields of study has consistently eluded the greatest scholars.

In physics as well as in other sciences, time is considered one of the few fundamental quantities. Time is used to define other quantities – such as velocity – so defining time in terms of such quantities would result in circularity of definition (Heathcote, 2004: 4). An operational definition of time, wherein one says that observing a certain number of repetitions of one or another standard cyclical event (such as the passage of a free-swinging pendulum) constitutes one standard unit such as the second, is highly useful in the conduct of both advanced experiments and everyday affairs of life (Lim, Huang, Puncher & Chen, 2007: 1832). The operational definition leaves aside the question whether there is something called time, apart from the counting activity just mentioned, that flows and that can be measured. Investigations of a single continuum called space time bring questions about space into questions about time, questions that have their roots in the works of early students of natural philosophy (Liverpool & Bryant, 2004: CDR.09.1). Time is (as in so many other cases) just as important in construction. Tompkins (1985: 54) puts the effect of time in construction in the right perspective when he states that "…few actually realize and utilize the true meaning of time".

Chassiakos and Sakellaropoulos (2005: 1115) point out that construction projects typically require time and effort to complete, several resources to be used, and a large amount of capital investment to spend. A particular objective for every project team will be to optimize the project duration. Gardiner and Stewart (2000: 251) indicate that projects are seldom completed in time and on budget. They mention values of "typically between 40% and 200%" of construction projects. Delays can have serious financial implications and can attract possible penalties, price increases, etc. which the contractor did not allow for initially. Figure 7.1 illustrates a typical project time management overview. Sappe (2007: 21) provides an example of the positive effects of an early finish on a construction project in the savings that were shown when the Hartsfield-Jackson Atlanta International Airport was delivered 11 days early and under budget by $102 million. The airport handled 976,000 flights and 88 million passengers in 2006 alone. It is easy to see the effects that even a one day early operational start will have on the income of such a facility.

Jiao and Tseng (1999: 739) comment on how improved time management can result in lowering product costs. Jenkins, Babuk and Mohitpour (2005: PM.13.1) express similar views. Zayed (2005: 667) and Zayed and Halpin (2005: 779) point out how increased productivity can enhance product value. The influences of productivity on construction cost have been discussed earlier in this study

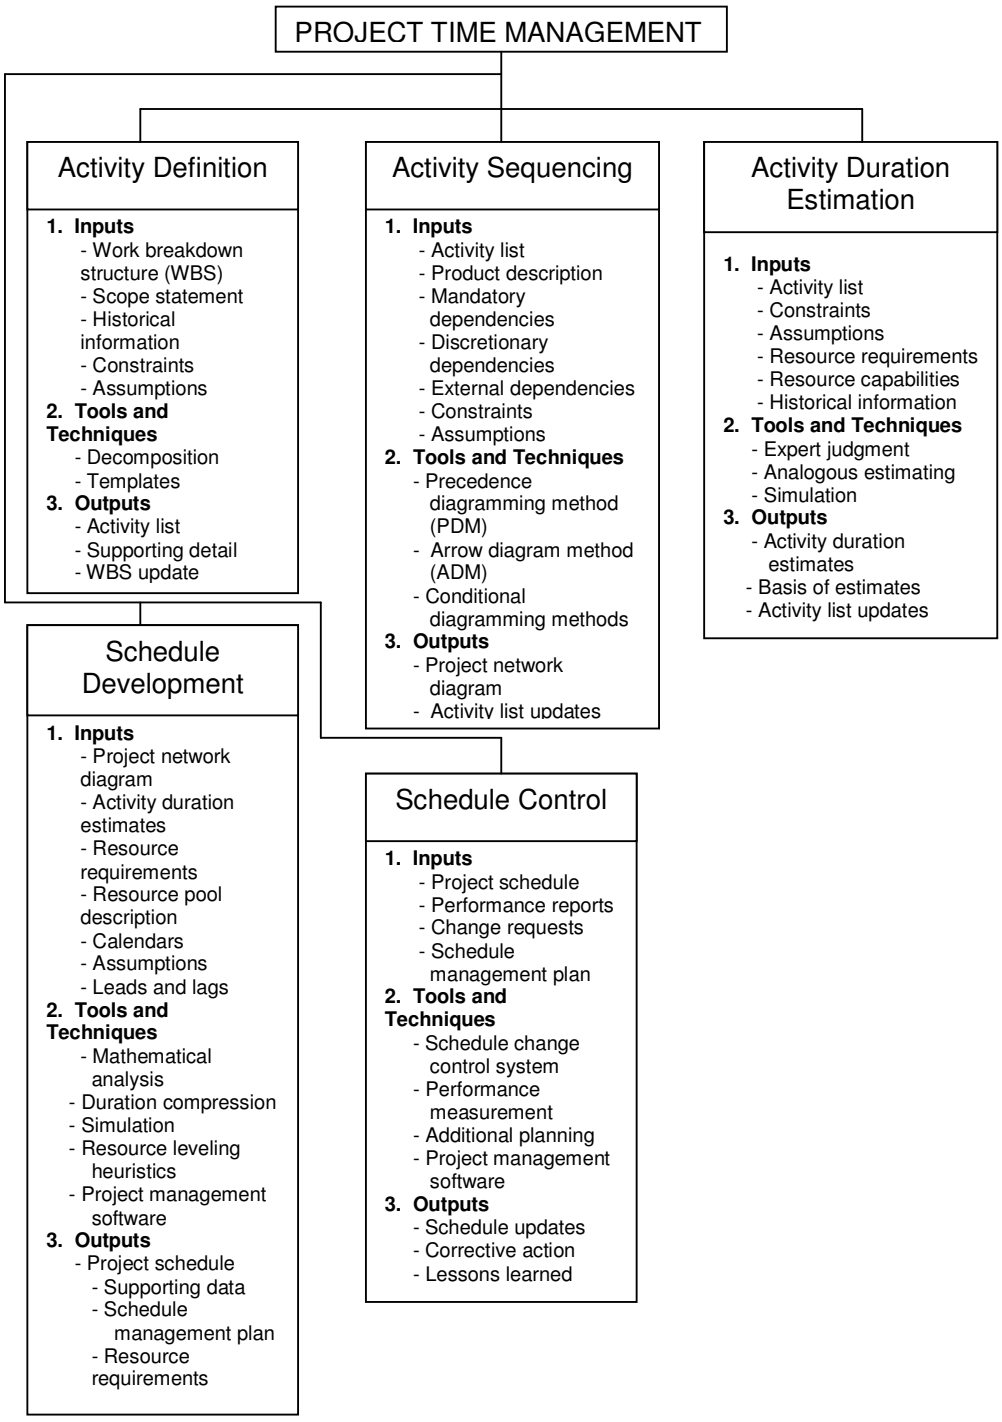

Figure 7.1: Project time management overview

Source: PMI , 1996: 60

Kim and De la Garza (2003: 510) state that the impact of time on construction cost necessitate good time management on the project and all necessary steps should be in place to capture any costs pertaining to extension of time (construction program) and acceleration. Farrow (2004: 1) and Farrow (2007: 218) demonstrate the importance of dealing with the cost implications for extension of time, and Singh (2003: 312) refers to the effect of acceleration due to efficiency losses either due to non-productivity or under-manning.

2.2 Time-cost optimization

Love *et al.*, (2005: 187) point out that cost has proven to be the most significant predictor of construction time. They recommend a simple equation which can be used to determine construction time. The equation proposed can be described as follows:

$T = KC_b$

Where:

T = duration of construction period from date of site possession to practical completion in working days
K = a constant describing the general level of time performance for a $1 million project
C = final cost of structure in millions of dollars adjusted to constant labour and material prices
b = a constant describing how the time performance is effected by project size as measure by cost

Horman and Kenley (2005: 52) describe the effect of wasted time in construction and Mazouk and Moselhi (2004: 878) comment on the effect of travel time for material and labour in construction. These are just some examples of what influence time has on construction cost.

With the rapid proliferation of the use of alternative project delivery systems, construction stakeholders are no longer focusing merely on minimizing cost alone, since time could also be a crucial variable in the bid evaluation and construction processes (Zheng *et al.*, 2005: 81). Compression in project duration would inevitably result in direct cost escalation, as extra labour and plant resources would be required

to expedite the works (Mitchell & Klastorin, 2007: 960). Time-cost optimization is a process to identify suitable construction activities for speeding up, and for deciding "by how much" so as to attain the best possible savings in both time and cost.

Hastak, Gokhale, Goyami, Hong and Safi (2007: 435) point out that since there is a hidden trade-off relationship between project time and cost, it might be difficult to predict whether the total cost (i.e. the direct and indirect costs) would increase or decrease as a result of the schedule compression. In reality, although the direct cost would increase as the project duration reduces, the indirect (overhead) cost, being a fixed daily cost, could fall. Zheng *et al*,, (2005: 81) hereby imply that there is a possibility that the lowest cost and the shortest time can be located synchronically.

2.3 Schedule forecasting and earned schedule analysis

Tompkins (1985: 54) refers to the generalized usage of the phrase "time is money", which is very relevant in construction. Since the cost of project time in the later phase of a project (e.g. the construction phase) is far greater than during the initial construction phase (e.g. the design phase), it is important to project cost success to have thorough planning at the beginning (Checkley, 1994: 21). He indicates that some project analysts have estimated the completion/start project time-cost ratio to be as much as 300 to 1. This ratio indicates that the time spent at the end of a project is approximately 300 times more expensive than time spent at the beginning of a project.

Changes later on during the project's life, impacts a greater number of personnel and also a greater number of hardware characteristics that may have already been designed, manufactured and/or fabricated (Kaka, Lewis & Petros, 2003: 16). The cost of design change has been discussed previously in this study. Tompkins (1985: 55) indicates that an equitable balance in initial planning and a healthy initial project inertia resulting from a quick start will achieve optimum project cost results. Figure 7.2 illustrates the process flow of a project and indicates how activities overlap to optimize project schedule.

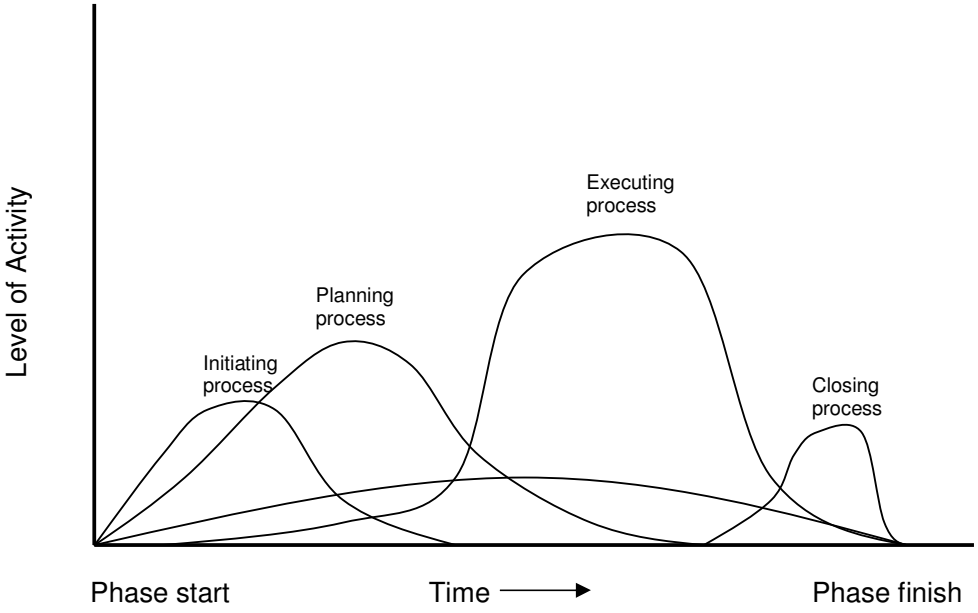

Figure 7.2: Overlap of activities in a project

Source: PMI, 1996: 29

Several project programming and scheduling techniques have been developed. Some are simple, such as the bar chart, and have been in use for the last century (Verveniotis, 2008: PM.02.2). While the more sophisticated methods were developed in the 1950s in America as a result of the advent of larger, more sophisticated industrial projects and the acceptance of computers. Consequently, present day management has several planning and scheduling techniques from which to choose (Winter & Calvey, 2008: PS.03.2). This, in itself, is a problem in that each technique has an optimum and it is possible to waste much of the project's budget in selecting and applying an inappropriate technique. Table 7.1 compares these techniques in the sequence they evolved.

Suggested plan / schedule technique	**Primary characteristics**	**Advantages / disadvantages**	**Example optimum application**
Bar chart	Use of graphically illustrated bars to control task time	- Project planning and scheduling and progress are graphically shown together making a	Repetitive type projects with low engineering contents or smaller one-of-

Suggested plan / schedule technique	Primary characteristics	Advantages / disadvantages	Example optimum application
		clear, simple account of the project. - Cannot show sufficient detail on long duration tasks to avoid schedule slippage - Task dependency relationships cannot be clearly shown - Manually updated	a -kind projects
Arrow diagram (activity-on-arrow)	Use of arrows to represent project tasks (activities) arranged so as to show task inter-dependency	- Project planning may be separate from scheduling unless the network is illustrated on a time scale - Greater project task detail available than bar chart - Clearly shows task interdependency - Changes in the duration of one task may require movement of following tasks on a time scale, thereby causing significant	Production planning or other applications where clarity of conflicting requirements is of primary importance; or projects of an intermediate size

Suggested plan / schedule technique	**Primary characteristics**	**Advantages / disadvantages**	**Example optimum application**
		redrawing time - Simpler than the precedence diagram	
Node diagram (activity-on-node)	Use of nodes to represent project tasks interconnected by arrows; reverse of the arrow diagram	- Eliminate the need for dummy arrows in the arrow diagram to connect false dependencies - More efficient and compact than the arrow diagram and easier to learn - More involved computational procedure than arrow diagram	Production planning or other applications where clarity of conflicting requirements is of primary importance; considered secondary in preference to the arrow diagram except when used on construction type projects where many activities are concurrent
Preceding diagram (Extension of Activity-on-node or Node Diagram)	Extension of the node diagram; Addition of elements such as lead / lag times	- Same as node diagram - Modifications provide greater flexibility and use than the node diagram	Production planning or other applications where clarity of conflicting requirements is of primary importance;

Suggested plan / schedule technique	**Primary characteristics**	**Advantages / disadvantages**	**Example optimum application**
			considered secondary in preference to the arrow diagram
Project evaluation and review technique (PERT)	Description of project event sequence and interdependency allowing determination of probability of meeting schedule	- Requires establishing project objectives and a method for determining how to achieve these reducing the risk of oversights - Provides clear documentation for communicating project plans and progress - Establishes interim objectives - Emphasizes the concept of management by exception - Allows determination of numerical probabilities associated with variances in project completion times	Applied research and development projects or other projects compromised primarily of activities whose duration times are subject to considerable variation
Critical path	Description of	- Similar to those	Design and

Suggested plan / schedule technique	Primary characteristics	Advantages / disadvantages	Example optimum application
method (CPM)	project event sequence and interdependency allowing determination of project time-cost tradeoff's	listed for PERT since both are considered critical path techniques - Allows determination of project task completion times which minimize total project cost	construction projects and maintenance programs
Graphical evaluation and review techniques (GERT)	A generalized arrow diagram incorporates techniques for network branching and looping	- Same as arrow diagram - Allows the evaluation of alternatives	Projects such as research which involves testing and recycling if testing results in failure; maybe used for project startup where rework may be necessary

Table 7.1: Comparison of scheduling techniques in sequence of evolvement
Source: Tompkins, 1985: 56

The project plan and schedule are developed in accordance with the phases of a project and in a similar manner as project costs. Initial project planning and estimating may be as coarse or as detailed as time permits during proposal development in accordance with the level of risk acceptable to management (Van der Horst, nd: 41). Project schedules and budgets developed later in the project must be detailed and thorough in order to succeed in project cost control (Stoy, Dreier & Schakher, 2007: 55). Figure 7.3 illustrates the logical evolution of project schedules and costs.

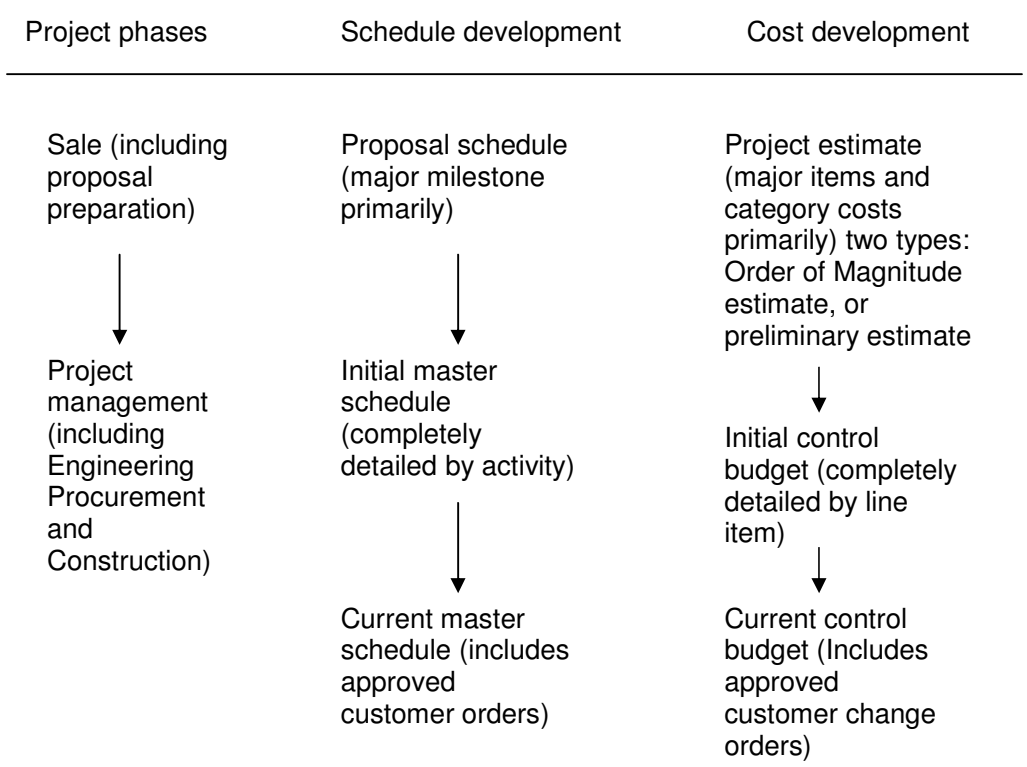

Figure 7.3: Project plan/schedule and estimate/budget development

3.0 HUMAN FACTORS IN FINANCIAL FORECASTING

Forecaster experience has long been believed to have a significant effect on the accuracy of construction contract price forecasts, and, therefore, on the development of the expertise that underlies professional judgment (Lowe & Skitmore, 2001: 485). Lowe and Skitmore (2001: 485) found that experience and expertise in price forecasting were perceived to be related to:

- The ability to select relevant price/cost data
- The ability to establish price/cost relationships and design parameters
- Intuitive abilities necessary for adjusting rates acquired through familiarity with projects

There exist a clear link between forecasting accuracy and the number of previous similar forecasts made by the forecaster (Burlton, 2001: 213). There is a relationship between several attitudinal variables and measures of forecasting bias, consistency and accuracy when performing forecasts.

Lowe and Skitmore (2001: 485) mention that when considering the possibilities for developing an expert system for price forecasting, there should be a clear link between forecaster experience, professional expertise and professional judgment. They also state that the “expert” is to use imagination, knowledge and experience to “fill in the gaps” within incomplete project information. Love, Ghoneim and Irani (2004: 312) indicate that in modern construction the availability of detailed project information (especially during the early stages of a project) is fast becoming a luxury. This puts increasing strain on the forecaster to rely more and more on his experience rather than project information to produce a reliable cost forecast (Rad, 2008: TCM.S01.2).

4.0 CASH FLOW FORECAST

Louw (2002: 218) states that the only way to properly perform cost control on a project is by means of a cash flow forecast. This is done as early as the first cost estimate and it is a natural action following cost estimating and project planning. The cash flow forecast will assist management to make important financial decisions should there be an indication of limitations to the periodic cash flow available (Le Roux & Cloete, 2007: 1; Checkley, 1994: 22). It may be necessary to revise the time schedule as a consequence of this or to increase the amount of period funding available. Chen (2007: PM.02.1) indicates that cash flow is where project costs meets the schedule. Cash flow models should be updated as soon as new/improved information becomes available.

As previously mentioned in this study, cost control should start as early in the project as possible. Louw (2002: 218) makes an important statement when he state that one is only able to control funds that have not yet been committed, thus it is clear that cost control should start during the conceptual design. This is because many of the costliest components of most projects are decided upon during the earliest stages of design (Brigham, Gapenski & Daves, 1999: 243).

The basis of the cost estimate should be critically examined by the project team for overdesign, excessive scope, duplications and omissions, and over- or under-estimation of contingency. Brigham *et al*., (1999: 244) indicate that this process of checking by the project team is sometimes referred to as ”squad checking”, and at the same times serves to communicate the scope of work as well as the basic philosophy about the project to the team members.

4.1 Cash flow models

Park *et al*., (2005: 172) state that essentially, a good forecasting technique needs to include both a historical trend-based data supported method and competent judgments based on construction experience. Park *et al.* (2005: 164) mention that cash is the most important resource in any construction business. More construction companies fail due to a lack of liquidity to support their daily activities than because of inadequate management of other resources (Chen *et al*., 2005: 669).

Different opinions on cash flow forecasting exist. It is better to engage in financial forecasting, even in the early stages of the project. There are many factors that exist during construction that may affect the cash flow including time delays, cost overruns, unconfirmed earned values, change orders and changes of cost plan elements. Odeyinka *et al*., (2008: 6) point out that the key points of cash flow forecasts lie in how accurate, flexible and comprehensive they are to be calculated and how effectively they consider uncertain factors such as time delay, cost overrun, variation of cost, and earned value between plan and actual. Even when construction is in progress, cash flow forecasts cannot be determined precisely. As a result, most models and techniques are found to have the following problems:

- they are not based on the construction stage, but rather on the planning or preliminary stages in the project delivery process;
- they do not consider time lags for the costs and earned values in forecasting cash flow, and;
- with regards to integration of cost items and activities, they are not compatible with each item and are rather complicated depending on when change factors occur in the subsequent construction stage.

4.2 Typical cash flow of a general contractor

Most construction projects are individual profit centres, each with its own cash cycle based on the costs of activities related to the project and on payments from a client, both of which are prescribed by a contract (Carlos & Formoso, 2006: 76). Typical cash flow on a construction project consists of:

- cash out - such as bid costs, preconstruction costs (engineering, design, mobilization, etc.), materials and supplies, equipment and equipment rentals, payments of subcontractors, labour and overhead, and;
- cash in - such as billings (less retention), claims and change orders.

Chen (2007: PM.02.1) illustrates in Figure 7.4 the difference between cumulative expenses and cumulative income. Chen describes the basic process of cash flow for a contractor in that the contractor takes time to put forward an invoice with the appropriate backup. The client will have to assess this invoice and certify payment. In the meantime, the contractor has to finance the project and interest is payable. This interest is normally recovered through overheads, fees or large upfront mobilisation charges.

The factors that affect cash flows are the duration of the project, the retention conditions, the times for receiving payments from the client, credit arrangements with suppliers or vendors, equipment rentals, and times of payments to subcontractors. The increasing difficulty to obtain credit is stressed by Beech (2006: 18).

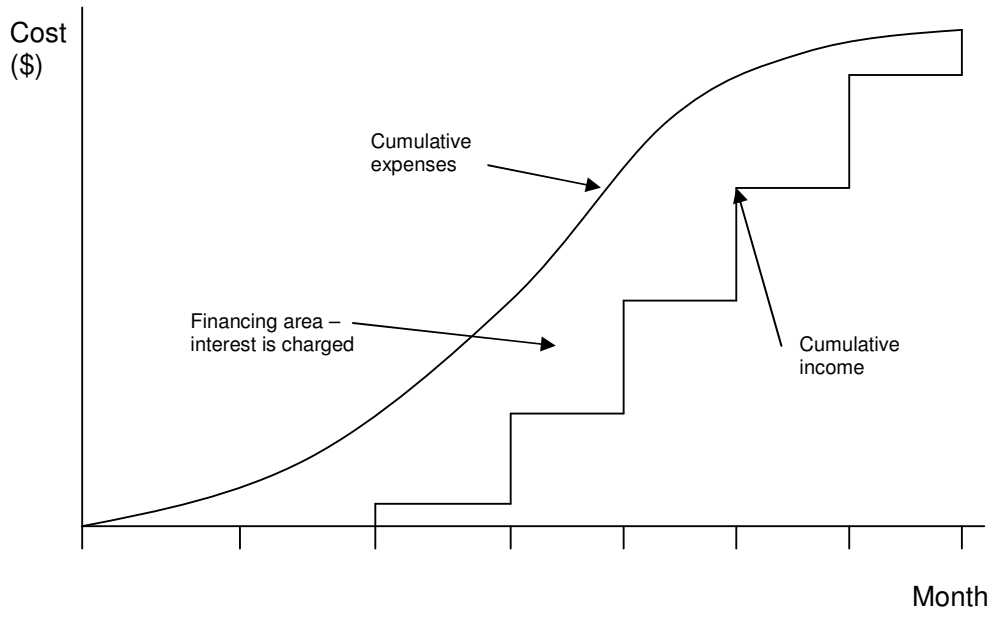

Figure 7.4: Contractor's project cash flow
Source: Chen, 2007: PM.02.1

Park *et al.*, (2005: 165) indicate that cash flow at project level consists of a complete history of all cash disbursements and all earnings received as a result of project execution. Many construction projects have a negative net cash flow until the very end

of construction when the final payment is received or advanced payment is received before starting the project. This is a typical situation when the final payment consists of retention money and the retention percentage is greater than the profit percentage of the project.

Probably the most important aspect of cash flow forecasting is to have the ability to determine or project the Estimated Final Cost (EFC) of the project. There are several variables affecting the EFC, such as time extension, etc. Chen (2007: PM.02.2) demonstrates how a typical man-loading on a petrochemical project will look. This situation is illustrated in Figure 7.5. The involvement of people on the project can clearly be seen in this graph. The trapezoidal approximation can be applied to most projects, except shutdown turnaround projects.

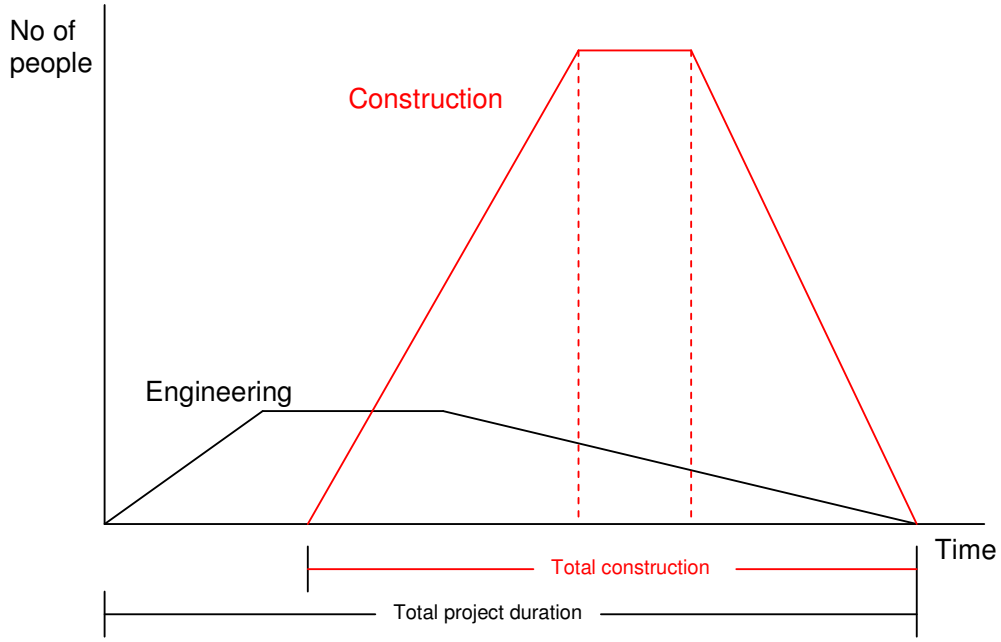

Figure 7.5: Engineering and construction resource profile approximation
Source: Chen, 2007: PM.02.2

5.0 DEVELOPMENT OF A PRICE FORECASTING MODEL

Newnan *et al.*, (2004: 39) point out that estimating or price forecasting is difficult because the future is unknown. It is sometimes impossible to forecast future economic trends and consequences of political actions or environmental occurrences. There also

exists a fine line between the trade-off between the costs of producing an estimate versus the accuracy of the estimate. Figure 7.6 illustrates this point.

Estimated parameters can be one-of-a-kind or first-run projects. The first time something is done, it is difficult to estimate costs required to design, produce and maintain a product over its life cycle. Newnan *et al*., (2004: 40) refer to projected cost estimates that were developed for the first National Aeronautics and Space Administration (NASA) missions. Initially the US space program had no experience with human flight in outer space; thus the development of the cost estimates for design, production, launch, and recovery of the astronauts, flight hardware and payloads was a "first-time experience". There are, however, few one-of-a-kind estimates to be made in engineering design and analysis. Nearly all new technologies, products and processes have been derived from similar concepts which led to their development.

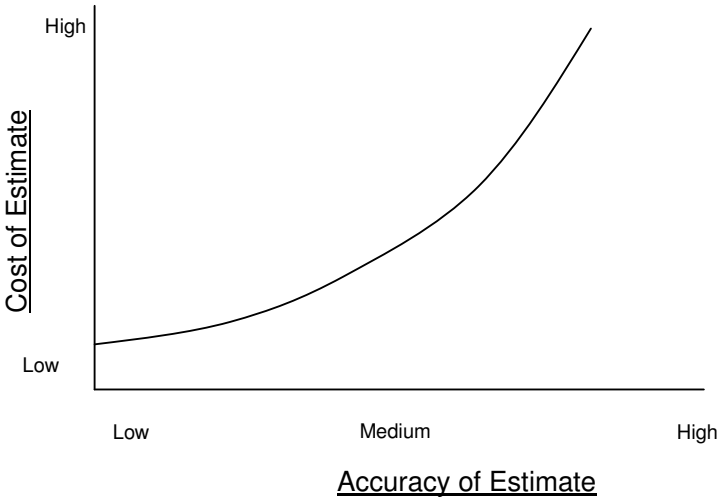

Figure 7.6: Accuracy versus cost trade-off in estimating
Source: Newnan *et al.,* 2004: 39

The ability to develop engineering estimates is constrained by time and personnel availability (Figure 7.6). To optimize the tendering procedure and maintain an acceptable strike rate when bidding on new work, the method of tendering or estimating should be such that all of the mentioned constraints are kept in mind. A similar chain of thought is applicable when dealing with projects that are currently being constructed should one need to determine the EFC of such a project.

Newnan *et al*., (2004: 40) used the axiom "*the past is our greatest teacher…*" when referring to the estimator's experience. This phrase is especially true when considering

ratio conceptual estimating which is based on historical data derived from completed projects. Throughout the financial forecasting process one would continually update the EFC to represent the latest available information. The use of the estimating principles, as set out in this study, must be employed here as well as when tendering on new work.

5.1 Pre-tender construction price forecasting

Skitmore and Drew (2003: 36) point out that pre-tender construction price forecasting refers to price estimating. Thus far, the bulk of this study has been dedicated to the principles of construction estimating (price forecasting) and the influences on estimate accuracy. The focus of this study is more towards conceptual price forecasting (estimating) and how this form of forecasting can be implemented, not only at inception of a project, but also during the course of the project's life.

Addendum E depicts a proposed format for a basic financial forecast on a specific contract within a project. This summary of costs on a dummy contract can be initiated even in the conceptual stages of the project. The estimated costs will then be listed and will be updated as the project evolves. The pre-tender construction price forecasting will therefore be represented by the estimating document. Firstly, the conceptual estimate and then at a later stage the detailed estimate will be used in this forecast.

5.2 Construction price forecasting

Construction price forecasting can commence as soon as the contract for the specific scope of work has been agreed on with the sub-contractor in question. This is normally when the contract with the sub-contractor has been signed. Price forecasting before this point in time would have been done, but it would be based on estimates. These estimated costs will be replaced during the construction period with actual contract amounts and other relevant increases. The following possible increases to the contract amount can occur:

- Contractual scope of work – Referred to in Addendum E as "measured work" is the amount for which the contract is signed and for which the contractor has agreed to conduct the scope as set out in the works information of the contract. In the case of a re-measureable contract, the

value of this work can increase or decrease depending on the extent of the remeasure. The remeasure gets done as the contract progresses.

- Extras – The example shown in Addendum E specifically refers to the New Engineering Contract (NEC) as this contract gets used more often in the engineering field. Terminology such as "Early Warnings" and "Compensation Events" is used in the NEC. These references are similar to the traditional variation orders. All these specific extras to the contract are listed and a cost is allocated against the item. All the costs add up and the total gets added to the overall total.
- Known Committed Costs (KCC) – KCC allowances are made in cases where no specific instruction has been given, but there is a likelihood that an event which might result in additional (or less) cost, can occur. Estimates are made, listed and added to the total.
- Contingency – Contingency analysis has been discussed in Chapter 6 of this study. The contingency will be added to the EFC to allow for unforeseen costs. This amount will be increased or decreased as the contract progresses, depending on the risk associated with the contract at a given point in time.
- Payment assessments – Addendum E shows the chronological sequence of the payment assessments and also depicts the percentage change between progressive payments and the original contract value, as well as the extended contract value.
- Contract status – Shows a summary of the aforementioned, briefly summarizing the EFC breakdown.

Detail of all the events is logged and the status of each event is indicated. When using modern spreadsheet software, formulas can be inserted to group all events according to status (Butts, 2007b: IT.07.1). By doing this, the "approved" extras can be added to the original contract value to calculate the extended contract value. The "pending" extras and the KCC's will be added together and be seen as future costs.

By adding the data for the previous report, one could determine the movement for the current report. There will always be the possibility that certain work should be back charged to another party. The back charge might have resulted due to mistakes made by the contractor in question due to incompetence or misinterpretation of the scope of work. These back charges are also logged on the summary sheet (as indicated in

Addendum E). Back charges are then reimbursed by deducting money from the total EFC for the specific contract.

6.0 RATIO CONCEPTUAL ESTIMATING IN FINANCIAL FORECASTING

The importance of continuously updating the EFC on the project has already been discussed. The emphasis of this study is to demonstrate the use of ratio conceptual cost estimating in the financial forecasting process. It is the very purpose of ratio conceptual cost estimating to provide early cost data, based on limited scope (Cheung & Skitmore, 2005: EST.14.1).

The first estimated final cost of the project will therefore be based on a ratio conceptual estimate. Thereafter it will evolve into a more detailed estimate and finally into a full detailed estimate. The process of estimating has been described earlier in this study.

Ratio conceptual estimating (RCE) also can be very useful during the course of a project to determine the EFC. There are several instances during the life of a project where certain scope has to be omitted or added, and in most cases the information available for this scope is limited. Should RCE be employed in these cases, the project team will be able to have an early benchmark which will allow them to improve their financial planning.

As previously stated in this study (Chapter 3), probably the most important aspect of cost estimating in any form is the scope definition of the work that needs to be estimated. To ensure that the correct scope is assessed in the RCE it is essential to make sure that all stakeholders are in agreement with the proposed scope of work. Addendum H illustrates a typical scope definition breakdown of a portion of a specific project. The basis of this breakdown is drawn from Addendum A and will be adjusted from project to project depending on the specific project requirements. Addendum I provides a simple estimate stakeholder scope agreement which needs to be signed off by all the relevant stakeholders to ensure that the complete scope as set out in Addendum H has been covered.

Chapter 5 of this study described the data collection process in petrochemical construction projects. If there is a proper database of relevant data on which RCE calculations can be based upon, this method of estimating can be used with good results, whether complete comprehensive additions are added to the plant (such as a

new sub-station building), or only relative small changes such as an additional gas line. Addendum D can prove as an example of such a database.

A petrochemical project is normally split into several major sections to divide the scope of work in manageable portions and to allow different contractors to tender on the work. A typical breakdown might look as follow: civil works, structural steelwork, mechanical and piping, electrical and instrumentation, and painting and insulation. Together with these smaller contracts there might also be things like MV switchgear, hazardous area classification, etc. as well as some professional services contracts.

Addendum F illustrates the use of RCE at the inception stage of a project. In this particular case only the civil works are detailed.

Even though the abovementioned breakdown of the RCE will serve as the basis for the EFC during the early stages of a project, it will be regularly updated as better information becomes available. During the course of the project, individual RCE's are done to determine the cost of possible additions or omissions. Figure 7.7 indicates how a fairly accurate estimate can be done in a matter of minutes, based on ratios and historical project data. This specific estimate is for an additional steel support structure.

RATIO CONCEPTUAL ESTIMATE – STRUCTURAL STEEL – REACTOR SUPPORT				
Project name:	XYZ Refinery			
Location:	Gauteng – South Africa

	Kick plates - erect	M	492.60	430.86	212,241.64	

Figure 7.7: Summary of Ratio Conceptual Estimate (RCE) for an addition to existing scope of a complex steel structure on a typical petrochemical project

In both cases depicted in Addendum F and Figure 7.7, the estimator only needs to complete the "Project detail" portion and the rest of the estimate will be computed automatically, based on the ratios as set out in Addendum D.

In this example, the only quantity that needs to be taken off the drawings will be the volume of the steel structure (4,500m³). The rest of the quantities are calculated by means of applying the ratios determined in this study. Similar estimates, as shown in Figure 7.7, can be done for any addition or omission to the scope. All the relevant ratios are set out in Addendum D. The application of the ratios and how quantities are derived from it is set out in detail in Chapter 8.

To determine the rates for the individual items a rate calculation can be done. This calculation is based on base rates (refer to Figure 7.8) and various independent influencing factors such as escalation. The adjusted base rate then is manipulated by using cost factors to calculate the required rate. The influencing factors are adjusted based on the facts and findings earlier in this study relating to these issues.

The information contained within Figure 7.8 will be adjusted on a regular basis as base rates change. This figure is similar to the one used in Chapter 5, but with the difference that this calculator is utilised to adjust base rates that will suffice under normal circumstances to suit the needs of the specific project in question. A complete example of how a RCE will be conducted and integrated into the financial forecasting system will be demonstrated in Chapter 8 of this study.

7.0 SUMMARY

The importance of time and the effect it has on society is evident in our daily lives. A construction project is similarly bound to the effects of time, especially from a financial point of view. The quicker the contractor can get off site and still maintain a good quality standard, the better for him. He will be better off financially in the sense that he does not have to keep on applying his resources to the project he is currently busy with, and he will be able to utilise the same resources on another project. Turnaround time is therefore important for any contractor. Proper planning, project management, quality control, etc. are all important aspects that should be kept in mind in order to reduce the time spent on site to complete the project. A further aspect which might come into play when delays are experienced on a construction site is the possibility of paying penalties. Such penalties are especially severe in the case of a plant that forms part of a critical chain of processes, or that is of environmental importance (Yang, 2007: 26).

The only way to keep track of the financial progress on a project is by means of a proper financial forecast and part of this forecast is the cash flow analysis. The

standard cash flow model reports on the in- and out flow of money for the project in question. The contractor should realize that on most projects he will operate on a negative cash flow, since the cumulative income will always be less than the cumulative expenses and he will only reverse this situation close to the end of the project. Negative cash flow is expensive as the contractor will have to finance the project to some extent.

An integral part of the financial forecast is the plotting of an estimated final cost. This cost represents the projected final account value. In many cases this is a complicated exercise because of the non-availability of scope detail. Fast track turn-key projects force the contractor to adopt methods that lend themselves to minimum scope definition and still produce a reliable financial forecast. One such method, Ratio Conceptual Estimating (RCE), is a method which, if applied correctly, can produce quick and fairly accurate estimates which can be used in calculating the estimated final cost of a project.

To apply Ratio Conceptual Estimating (RCE) it is required to make use of reliable ratios which are based on a database. The development of such ratios and the application thereof in the estimate gets discussed in the next chapter.

CHAPTER 8

PRACTICAL APPLICATION OF RATIO CONCEPTUAL COST ESTIMATING

1.0 INTRODUCTION

Ratio Conceptual Estimating (RCE) is a quick form of cost estimating based on a historical database and ratios derived from this database. The better the quality of the database, the better the end result of the estimate.

It is however not only at the beginning of a project where RCE is utilised to conduct estimates. There are many instances during the course of a project where RCE can be used to conduct estimates to check budgets or to determine budgets for certain additions to the project. The use of RCE in the financial forecast is one such example. The purpose of the financial forecast is to report to management the forecasted financial commitments for each project. New scope should therefore be cost in such a way that it is quick, but also accurate enough to fall in line with a Level 4 estimate (refer to Chapter 2 of this study).

As mentioned previously, RCE can only be done if a proper database exists. To proof the value of RCE in the petrochemical industry, a database has been developed and included in this study. Refer to Addendum D. It is however necessary to analise this data and to put it in such a format that can be used in RCE. The practical application of RCE can be much enhanced by the use of computer software and if based on a proper database, can provide fairly accurate estimates quickly.

2.0 FINANCIAL FORECASTING AND RATIO CONCEPTUAL COST ESTIMATING (RCE)

It is clear from theory discussed in Chapter 2 that proper cost control during the course of a project is not a “nice to have” but a necessity. Project profit forecasting is, however, an important management function that needs to be performed to guide the project team as to what returns may be expected from the project in question. Profit forecasting begins at project level where historical project expenditures and predicted future commitments are scheduled. It will be the general aim of such a forecast to strive

towards predicting the final account value of each individual contract, and to attempt to get these values as accurate as possible.

The layout of a typical financial forecasting summary is set out in Addendum E where project progress can be followed through current expenditures. Minimisation of cost overruns can be done through early detection and redirection. Chapter 7 demonstrates the use of financial forecasting. The use of Ratio Conceptual Estimating (RCE) in financial forecasting is unavoidable since the speed of the financial forecasting process does not allow for more detailed estimating methods.

2.1 Improving the financial forecast by applying RCE

Scope definition is considered to be the most important aspect when doing any cost estimate. It is essential that the estimator is well aware of the scope of work, in other words what needs to be allowed for in the cost estimate. Addendum A has been included in this study to demonstrate what a typical generic scope breakdown would look like. The information contained within Addendum A was gathered over many years and will serve as a good guide for any estimator working specifically in the petrochemical industry.

The use of Addendum A and additions to this document will to a large degree eliminate some problems that might arise during scope definition. Grey areas and interfacing between certain portions of the plant will be minimised. Most importantly, incomplete scope definition due to overlooked elements of the scope will be reduced to such an extent that should there be any items that have been omitted during scope definition, the cost impact of those items should be minimal. Furthermore, Addendum A will also be helpful in the case of scope expansion or scope changes which occur in every project.

Ratio Conceptual Estimating (RCE) can be used throughout the lifespan of the construction project. Even smallish scope adjustments can be included by means of micro RCE's where portions of the database get applied. The size of the estimate does however not dictate the process of the estimate. The basic process of this form of cost estimate remains the same irrespective of the application thereof. The next portion of this chapter deals with the practical use of this form of cost estimation.

3.0 RATIO CONCEPTUAL COST ESTIMATING – THE PRACTICAL APPLICATION

Chapter 5 of this study refers to the collection of data and how to build a data base that can be used as a basis of a RCE. Addendum D contains the quantity and cost data of 45 projects in the petrochemical industry.

3.1 Discussion on data as contained in Addendum D

Addendum D contains the raw data taken from 45 actual projects' final accounts. These projects have been chosen as typical petrochemical construction projects and represent the norm throughout the petrochemical industry. Due to secrecy agreements, the detail of these projects (names, whereabouts, clients, etc) can not be revealed.

The bulk of Addendum D contains summaries of the quantities and rates for 45 different projects. Each project's detail has been listed in a similar fashion starting with "Bulk earthworks" and ending with "Electrical and Instrumentation". The quantities and rates used were taken from the individual agreed final accounts of each contract.

Also shown in each Project Summary are the ratios which have been calculated. These ratios can either be "quantity ratios" or "rate ratios". Each individual ratio has been given a specific name and this name is the same for all 45 projects. If one for instance refer to Project 1 (Addendum D – page D24), the ratio "AB-Q1" has a value of 1,35 and refers to the quantity ratio between "Bulk excavation" and "Trimming of sides". In other words; item "AB1.1" and "AB1.2". The simple formula for this calculation is shown on the right hand side of each ratio. The answer (ratio) has been rounded off to the second decimal place. All ratios for each project have been calculated in this fashion.

The ratios calculated in the individual project summaries as described above, have been transferred to a summary which is shown on page D1 to D22 of Addendum D. These quantities have been derived from the raw data and will be statistically adjusted for inclusion in the actual ratio database. Please refer to this adjustment process elsewhere in this chapter.

Page D23 of Addendum D is a summary of the variable conditions on each of the 45 projects from which data has been collected. Fourteen variables had been chosen based on the theory contained in earlier chapters of this study. They are as follow:

- Material (Type of material used)
- Labour (Availability of labour and skills at the time of construction)
- Engineering design (Complexity of the engineering design)
- Current economic conditions (Current economic conditions at the time of construction)
- Current economic factors (Current economic factors at the time of construction)
- Scope definition (Level of scope definition at the time of construction)
- Rework (Amount of rework that was done on the project)
- Scope change (Level of scope change that occurred on the project)
- Weather (General weather conditions at the time of construction)
- Access (Access to the site when the project was executed)
- Project size (Size of the project)
- Project conditions (General project conditions at the time of construction)
- Complexity (Complexity of the project in general)
- Repetition (Level of repetitive work that occurred)

The summary on page D23 lists the variables on all 45 projects. Each variable has three categories in which a project can fall. The decision of category allocation per variable and per project was made by the relevant project managers and site managers that worked on each of these projects. No scientific methodology was followed to allocate positions on this scale. Interviews with the various roll players revealed the situation as depicted on page D23.

3.2 Statistical analysis of raw data

Pages G3 to G32 contain the statistically altered ratios that were used to perform the RCE's on the target or sample projects (10 in total). The application of these ratios will be discussed later in this chapter. What is of importance here is to note that these ratios are not the same as the ones derived in Addendum D. The ratios calculated in Addendum D are the actual ratios based on historical data. The ratios on pages G3 to G32 are the statistically adjusted ratios which have been used to do RCE's for the ten sample projects (Addendum G). The process of deriving at the ratios set out on pages G3 to G32 need however to be discussed.

3.2.1 The research process

The role of statistics in research projects is set out in Figure 8.1. The steps in the process where statistics plays a role are marked with a dark out line. The process can be divided into five steps.

3.2.1.1 Planning

Steyn, Smit, Du Toit and Strasheim (1994: 3) pointed out that no research project of any significance can be conducted without proper planning. In the planning stage it is firstly important to formulate the purpose of the study as good as possible. To be able to reach this goal, it is important to extract certain information from a source. It is important however only to obtain the relevant information that is needed to fulfill the study's requirements.

3.2.1.2 Data collection

Physical data collection will not pose to be a problem if the planning has been done properly. The availability of data is dependant on the type of research conducted. More information on data collection is provided in Chapter 5 of this study.

3.2.1.3 Data normalisation and coding

Chapter 5 also contains information on data normalisation and how this can be done in the petrochemical construction industry.

3.2.1.4 Analysis

During this part of the investigation, statistical methodology are utilised to analise the gathered information. The first step in this process is called "descriptive statistics". Graziano and Raulin (1993: 90) describe three important groups of descriptive statistics; frequency counts and frequency distributions, graphical representations of data and summary statistics. Steyn, *et al* (1994: 5) expresses their view on descriptive statistics as follows:

> *"Descriptive statistics refer to the arrangement and summary of data by means of tabulating graphical presentation and the calculation of*

> *descriptive measures. By doing this, the inherent tendencies and properties of the gathered data can be shown."*

The second step in the investigation is referred to as "statistical intervention". Steyn, *et al* (1994: 5) refers to it as follows:

> *"Statistical intervention forms assumptions pertaining to the population from which the data has been drawn by utilising the descriptive measures that have been calculated."*

3.2.1.5 Conclusions

Once the statistical analysis has been conducted, important conclusions can be drawn in the form of a report. In this report it is important to answer as many of the questions that have been mentioned in the problem statement of the study. This step normally leads to further research.

3.2.2 What methodology to use?

Coetzee (personal interview: 01-09-2011) pointed out that the data pool of this study is too small (only 45 projects – refer to Addendum D) to apply significant statistical analysis. Although this number of projects (from a South African perspective) seems to be very few, it nevertheless represents the bulk of the petrochemical projects that were constructed in the past number of years. Bellamy (2011: 11) also stressed that for certain types of statistical analysis one require more data sources to establish meaningful results or to be of statistical significance.

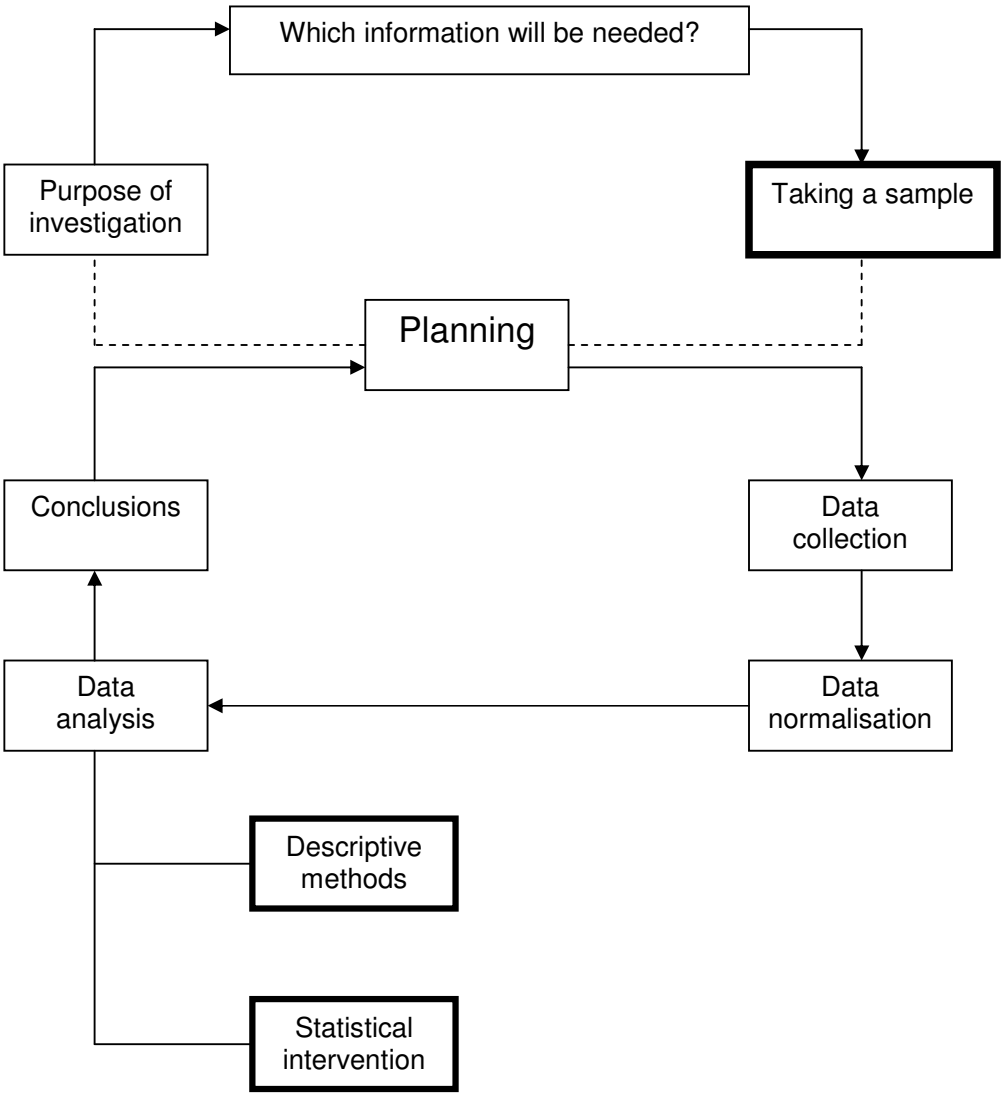

Figure 8.1: The role of statistics in research projects

Source: Steyn, *et al* (1994: 4)

Graziano and Raulin (1993: 97) pointed out that the measures of central tendency describe the typical or average score. They are called measures of central tendency because they provide an indication of the centre of the distribution where most of the scores tend to cluster. There are three measures of central tendency used to describe data; the mode, the mean and the median. The mode being the most frequently occurring score in the data field. The mode has the advantage of being simple to determine, but the disadvantage of being easily influenced by the change in one or two scores. Coetzee (personal interview: 01-09-2011) indicated that the use of the mode in this study is questionable seeing that the data field is too small.

To apply basic statistical analysis to the raw data it will be necessary to understand what the implication of certain formulas will be and how these formulas are being derived at.

3.2.2.1 Arithmetical mean

Graziano and Raulin (1993: 98) describe the mean as the “arithmetical average” of a particular set of scores. Steyn, *et al* (1994: 101) pointed out that this form of statistical indication is the most common form in use to indicate central tendency. The formula to determine the arithmetical mean is as follows:

$$\mu = \frac{\Sigma x}{N}$$

The addition of extra information into the data set will not have a significant influence on the value of μ. The smaller the data set, the greater the effect will be on μ, should there be any changes to the data set.

When the data set as set out in Addendum D is considered, the calculation for quantity ratio AB-Q1 (page G3) will be as follows:

$$\mu = \frac{\Sigma x}{N} \quad \textit{therefore} \quad \mu = \frac{98{,}21}{45} \quad \textit{therefore} \quad \mu = 2{,}18$$

The above calculation had been done to obtain all the “means” for the all the applicable ratios. The answers can be viewed on pages G3 to G32 Addendum G in the column headed “Project Ratio Mean”. The raw data can be obtained in the ratio summary of Addendum D.

3.2.2.2 Median

The median can be described as the fiftieth percentile of a data set. In other words, 50% of the values will be lower than the median and 50% will be higher. To determine the median, the values of a particular data set must be arranged from the lowest to the highest value. The value in the middle will then be the median. Steyn, *et al* (1994: 103) propose the following formula to calculate the median:

$$Median = \frac{n+1}{2} \text{ th value}$$

When considering the data in Addendum D, one can for instance (by applying the above formula) determine the median if all the data inputs are arranged from the lowest to the highest value. If the same ratio (AB-Q1 on page G3) is considered, the median will be 2,20. All the medians from the data of the 45 projects discussed in Addendum D, have been tabulated in Addendum G (page G3 to G32) under the heading "Project Ratio Median". All these medians had been calculated in the manner described above.

3.2.3 Applying the effects of the fourteen variables

The study of the theory pertaining to conceptual estimating (as described in Chapters 2 to 7 of this study) has revealed some factors that might influence the ratios calculated in Addendum D. These influences or variables have been summarised in Addendum D on page D23. There are fourteen in total.

Discussions have been held with several people that were involved in the 45 subject projects from which data had been drawn. Based on these discussions and a study of each project's detail, a position on the chart (page D23) had been allocated. These positions have not been calculated scientifically and were merely allocated based on what the project team and the project data revealed.

The summary of all the means and medians (pages G3 to G32) in Addendum G has been divided into fourteen major groups, based on the fourteen variables stated on page D23. Each group has been divided into three sub-groups ranging from "easy / little" to "normal" and finally to "complex / volatile, etc". Please refer to Addendum G to study the relevant column headings. Each sub-heading has again been divided into two separate columns named "mean" and "median".

To demonstrate how these values have been calculated, ratio AB-Q1 can be considered. Addendum D (page D23) reveals that the "material" variable can be spread as follows:

Material – Simple	-	9 Projects
Material – Normal	-	28 Projects
Material – Complex	-	8 Projects

Of the 45 subject projects there were 9 projects which material supply was considered to be “simple”; 28 projects had “normal” material supply constraints and 8 projects had rather “complex” material supply constraints. To determine the means and medians for the 9 projects which had few material supply constraints, the 9 projects had to be identified (page D23) and only their data had to be considered. The values of AB-Q1 in these 9 projects with “simple” material constraints were:

Project 3	-	AB-Q1 = 2,83
Project 9	-	AB-Q1 = 2,03
Project 17	-	AB-Q1 = 2,36
Project 23	-	AB-Q1 = 2,29
Project 24	-	AB-Q1 = 2,14
Project 29	-	AB-Q1 = 2,37
Project 30	-	AB-Q1 = 2,21
Project 31	-	AB-Q1 = 2,06
Project 40	-	AB-Q1 = 1,98

If the formulas described above are applied, the mean and median for this data set can be calculated. The mean for ratio AB-Q1 for the nine projects stated above is therefore 2,25 and the median is 2,21. These values have been entered into the ratio summary (page G3 to G32) of Addendum G under the “Material” heading, with a “Simple” constraint level. The rest of the ratios for variable changes have been calculated in a similar fashion.

3.3 Application of data on real life projects

To test the integrity of the data that is expressed in Addendum D and reworked and tabled in Addendum G, it will have to be applied to actual projects. The end results will then have to be compared to the actual costs (final account values) of these projects. The difference between these values will be an indication of just how applicable the data will be when employed in RCE. Again, the detail of the target projects can not be revealed due to secrecy agreements.

Ten typical petrochemical projects have been chosen and cost estimates for these projects had been done for these projects. The estimate method utilised was Ratio Conceptual Estimating (RCE). The variable characteristics of each project were tabulated and can be viewed in Addendum G on page G2. The quantities and rates applicable to these projects have then been calculated to form the basis of the estimate.

3.3.1 Discussion on the application of Addendum G

The detail of the ten target projects has all been listed in Addendum G from Project A to Project I. Once the ten chosen projects had been identified and their variable characteristics tabulated (refer to page G2), some basic quantities were taken off. These quantities were measured from conceptual design drawings and were then entered into a computer spread sheet as can be seen on page G-A1. The base rates utilised, were market related when considering the specific target project in question.

A breakdown of all the quantities for each of the ten projects had been prepared. The breakdown of Project A, for instance, can be found on pages G-A3 to G-A28. This breakdown is summarised on page G-A2. The same process was followed for all of the ten projects.

The spread sheet was developed in such a way that it is completely formula driven. The breakdown of the quantities, rates and totals on pages G-A3 to G-A28 have all either been calculated by means of formulas or were drawn from the information page which in the case of Project A, can be found on page G-A1. The shaded cells in the breakdown (pages G-A3 to G-A28) indicate quantities and rates that have been drawn from the information page (page G-A1 in the case of Project A). For instance, the “Site clearance” for Project A of 16,500 m² (shaded cell on the top of page G-A3) was directly taken from the information page (page G-A1). This quantity has in other words been measured off drawings and entered (by hand) into the information page.

The population of the information page is done by entering gathered information which then get utilised in the formulas throughout the spread sheet. The rates in the information page are the market related rates at that given point in time. The ten projects in question had been completed at different times; therefore different rates were used. The population of the break down for Project A (as shown on page G-A3 to G-A28) happen by means of formulas which utilise the information on the information

page as well as the statistically altered ratios (refer to the appropriate section in this chapter).

When the “Trimming of sides” for instance on Project A gets calculated; the ratio named AB-Q1 with a value of 2,18 had been used. In this case, both the “quantity ratio” and the “rate ratio” are the statistical “mean”. The relevant ratio to use can also be chosen on the information page of the estimate. In this case it is page G-A1. Depending on the choice made by the estimator (at the bottom of page G-A1), the computer will automatically apply the correct ratios (according to the table in Addendum G) to the measured quantities and rates also inserted on the information page, which will then (by means of formulas) populate the estimate break down (pages G-A3 to G-A28). All the un-shaded areas in each of the projects’ break downs represent a value which has been calculated by applying the appropriate ratio to another quantity or rate. How these ratios have been calculated can be viewed in Addendum D.

3.3.2 Outcome of application of statistically altered data

As previously mentioned, the variables for each of the ten target projects have been shown on page G2. These variables have been utilised to make adjustments to the data utilised in calculating each end cost. The cost summary of the sample projects is shown on page G1 of this study.

The summary on page G1 indicate the outcome of a RCE that was conducted on each of the ten sample projects utilising the “mean” and “median” ratios as well as the “mean” and “median” variable ratios.

Table 3.4 in Chapter 3 indicates the typical accuracy range for the different estimate classes. If this table is compared to the results on page G1, it will be found that most of the ten projects’ results fall well within the Class 3 and Class 4 accuracy range. The application of RCE based on the data set-out in Addendum D can therefore deliver cost estimates with the average accuracy as set out in the small table at the bottom of page G1. These results are in line with the requirements for a conceptual cost estimate as previously set out in this study. Refer to Chapter 3 for more information.

If the “average accuracy findings” (bottom of page G1) is studied, it will be noticed that the ratio with the best results (fluctuating the least) is the “variable median”. With an

average estimate value of 0,7% more than the final account value. This value is however only an average and to get a better understanding of the actual values obtained, one should study each project summary (page G1).

The difference in results between the “mean”, “median”, “variable – mean” and “variable – median” is so small (page G1), that it can hardly be considered as meaningful. The allocation of variable classification as set out on page G2 is also done in a non-scientific manner and is based on the experience of the team involved. By allocating the incorrect variable classification to the variable in question, will influence the end-result of the estimate. Seeing that the difference between the “mean” and the “variable – mean” as well as the “median” and the “variable – median” is so small, the implication of “variables” remains questionable and it seems that in this case, the application thereof is not necessary.

From the results stated on the summary page (page G1) it is clear that the “median” ratios provided better results than the “mean” ratios. The average difference between the final account values and the estimated values, when using the “median”, is 3,20%. This means that the application of RCE (using “median” ratios) resulted in a 3,20% higher estimated final cost, while the application of the “mean” ratios resulted in an average 5,46% lower cost. Although both sets of data provided good results, it seems that by making use of the “median” ratios will result in slightly higher end results, which for estimating, is beneficial.

4.0 SUMMARY

The practical application of Ratio Conceptual Estimating (RCE), if based on a properly developed database, can be successfully incorporated into the estimating process on a petrochemical project. This can either be done at tendering stage or it can be used as a management tool to forecast costs for additional scope. This is particularly of importance when conducting the financial forecast on the project.

In this study a subject project list of 45 projects have been used to create a database from which quantity ratios and rate ratios have been derived. Refer to Addendum D. Statistical analysis of these ratios provided a set of ratios (based on “means” and “medians”) which have been summarised and used to conduct actual estimates of ten projects. The results have been compared and found to be fairly accurate, which is well in line with the requirements of a conceptual cost estimate.

CHAPTER 9

CONCLUSIONS, LIMITATIONS AND FUTURE RECOMMENDATIONS

1.0 INTRODUCTION

The purpose of this chapter is to draw conclusions from the application of the data based on the theory basis provided in Chapters 2 to 7. Conclusions are drawn in accordance with the research objectives. Furthermore, limitations of this study are discussed and recommendations are made for the petrochemical construction industry. Finally, research opportunities that emanate from this research are presented.

2.0 CONCLUSIONS

Next, the conclusions of the empirical studies are drawn.

An abbreviated synopsis of the main points drawn from the study can be listed as follows:

- Cost control on construction projects is essential for the success of the project and monitoring of cost should be done throughout the life cycle of the construction project.
- Good cost estimating procedures will provide a solid base for the construction budget and a reasonable target by which the project can be controlled from a financial point of view.
- Scope definition is probably the most significant factor when any cost estimate is made.
- If conceptual cost estimates are conducted properly and if it is based on reliable databases, it can be a very useful tool in project cost control.
- Although conceptual estimates are considered to be a quick form of estimating, its success is largely based upon the quality of the database from which information is drawn. Setting-up a quality database takes a lot of time, but the dividends of this exercise will be realised in future estimates.
- Cost escalation and contingency analysis form an integral part of the estimating process and special emphasis should be put on these factors when the risk associated with the project is high.

- Financial forecasting is essential for the success of the project as it provides a monetary target that can be used to by management to measure the profit / loss forecast on the project and to report accordingly.

The primary objective of this study was to prove the effectiveness of Ratio Conceptual Cost Estimating (RCE) in the South African petrochemical construction industry.

Today, much more than ever before, financial success of any construction project, becomes more and more a result of scientific and precise evaluation of imposing factors and management thereof, than just informal decisions by management. Much creative thought should be put into the process of mitigating financial risks. It will be the contractor which excels in this, that will eventually be successful. Competition in the market is tough and work in the petrochemical construction industry is scarce.

To reach the goal mentioned in the previous paragraph, certain tools should be used to firstly allow management to get reliable answers and secondly to provide these answers at a reasonable level of accuracy. The time available to provide these answers is limited and to keep within the set program, the construction team on a given project should revert to methods which are economical when considering the time that they have at their disposal.

One such method that can be employed in financial forecasting is Ratio Conceptual Cost Estimating (RCE). RCE is a quick form of cost estimating and can be done fairly accurately. The purpose for which it is intended is to provide “check” estimates or basic estimates to adjust financial forecasting or to allow management to react to certain costs pertaining to scope adjustments on a project. RCE will however only be successful if it is based on a proper database which will take a considerable amount of time to establish, but once this is done, it will serve its purpose for a long time. Additions and adjustments to the databases can be made on an ongoing basis.

The petrochemical construction industry is no exception when it comes to dealing with cost forecasts. The results indicated in Chapter 8 of this study, showing the comparison between the ten target projects and the actual final account values of these projects, demonstrate that:

- firstly, the process of RCE can successfully be employed in the South African petrochemical industry, and

- secondly, the databases of 45 projects from which data has been drawn to derive at the ratios used in the RCE process, can be considered to be reliable.

Considering the above and especially taking into account the above bullet points, it is considered that researcher has reached the primary objective of the study and proved that RCE can successfully be utilised in the South African petrochemical construction industry.

The Secondary Objective of the study was to proof the value of Ratio Conceptual Cost Estimating (RCE) during the financial forecasting process.

Research mentioned in Chapter 7 of this study indicated the importance of financial forecasting. A study of the methodology of financial forecasting will reveal that the process of putting a future value to a particular scope of work, is nothing more than a range of small, medium and large cost estimates, combined into one exercise.

The time in which these estimates can be done is normally very limited as the financial forecast is done during the course of a project's life cycle. The scope is normally not well defined as the engineering of it is still in process. The limited level of scope definition together with the short duration in which these estimates can be done, makes the use of conceptual type estimates essential. RCE is one such method that can be used.

The nature of petrochemical plants is such that the lay-out and design criteria for most of these plants are similar. Taking this into consideration, it makes sense to make use of a system where ratios derived from previous projects, are used. RCE lends itself to this form of estimating and with a low level of available information; fairly accurate estimates can be compiled and included in the financial forecast.

Considering the fact that the Primary Objective of the study has been reached and that the contribution that RCE can have in the South African petrochemical construction industry, have been highlighted; conclusions can also be drawn regarding the use of RCE in financial forecasting. If RCE can be positively employed in conducting cost estimates for new petrochemical plants and the accuracy of these estimates is satisfactory (refer to Chapter 8), this form of cost estimating can also be used in the

costing of smaller portions of work. This has however not been proved in this study and remain open for discussion or for future research.

3.0 TESTING THE HYPOTHESES

This study researched, in particular, the use of Ratio Conceptual Cost Estimating (RCE) in the South African petrochemical construction industry. The Primary Hypothesis was mentioned in Chapter 1 as:

It is possible to apply Ratio Conceptual Cost Estimating (RCE) in the South African petrochemical construction industry.

From the interpretation and application of the theory of Chapters 2 to 7, Chapter 8 has been developed. In this chapter the process of RCE had been applied to ten typical petrochemical target projects. This process of RCE was based on a database derived from 45 historical projects (Addendum D). The results for the application of RCE in this instance are described in Chapter 8. When considering previous research, the international accepted level of accuracy for conceptual cost estimates is approximately 15% within the actual cost of the project.

The results obtained and described in Chapter 8 are well within this range of accuracy. Refer to Addendum G (page G1) for more information. Taking this into consideration, the primary hypothesis is supported.

The Secondary Hypothesis stated in Chapter 1, read:

The use of Ratio Conceptual Cost Estimating (RCE) in the construction of South African petrochemical projects will lead to improved cost forecasting.

The essence of cost forecasting lies in the timely prediction of future costs on a construction project. The purpose of cost forecasting in itself is to forewarn management of shifts in the projected cash flow to enable budget shifts or re-application of funds.

A cost estimate is nothing more than a prediction of what a particular exercise will cost at some point in time. A series of estimates of various sizes will be required throughout the lifespan of a construction project. The availability of engineering data and the

limited time available will necessitate a quick form of cost estimating. RCE does lend itself to these characteristics. Although the value of RCE in the South African petrochemical industry has been proved in this study, the specific application in smallish estimates (which normally forms part of the financial forecasting process) has not been tested. The secondary hypothesis is therefore not supported.

4.0 LIMITATIONS

Although the data pool seems to be quite comprehensive, it is actually not big enough to draw meaningful statistical analysis from. It will be many years before enough data sets exist for such analysis to be conducted. Competitive tendering procedures in the open market enhance this problem, seeing that many competitors do not want to surrender any information as they feel that this might compromise their position in the market place.

The size of the data pool of South African petrochemical projects poses to be the single most significant draw back of the use of RCE. This situation will improve over time as more projects are being constructed.

5.0 FUTURE RECOMMENDATIONS

Although the Primary Hypothesis has been supported, there are still areas where future research will add value. These areas can be summarised as follow:

- Although the use of RCE in South African petrochemical construction projects has proved to be successful when determining the cost of new plants, it has not been applied to small portions of scope additions / omissions. Future study may prove that similar databases (as stated in Addendum D) can be utilised to perform localised estimates.
- The current form of the database only caters for “installation” of items such as piping and mechanical equipment. Should the database be further developed, the “supply” of these items can also be included in the estimate.
- The development of locational factors which might be brought into the calculation might also be considered. The frequency of plants constructed in areas other than the traditional locations in South Africa, is however limited and the researcher will struggle to obtain a sufficient data pool.

THE USE OF RATIO CONCEPTUAL COST ESTIMATION FOR PETROCHEMICAL CONSTRUCTION PROJECTS IN SOUTH AFRICA

by

WILLEM PETRUS SMITH

submitted in accordance with the requirements for the degree of

PHILOSOPHIAE DOCTOR

in the

FACULTY OF NATURAL SCIENCES

DEPARTMENT OF QUANTITY SURVEYING AND CONSTRUCTION MANAGEMENT

at the

UNIVERSITY OF THE FREE STATE

2011

PROMOTER: PROF. H. J. MARX

(Volume 2 of 3)

ADDENDUM A

ESTIMATING CHECKLIST FOR CAPITAL PROJECTS

1.00		LAND AND SITE DEVELOPMENT
1.01		**Land acquisition**
1.01.01		Purchase
1.01.02		Freehold
1.01.03		Leasehold
1.01.04		Rental
1.01.05		Development grants or tax concessions obtainable
1.02		**Rates, taxes, stamp duty, levies, tariffs**
1.03		**Lump sum contributions to local authorities**
1.04		**Compensation for damage**
1.05		**Fees (e.g. Legal)**
1.06		**Access to site including wayleaves and easements**
1.06.01		Roads
1.06.02		Footpaths
1.06.03		Rail tracks
1.06.04		Conveyors
1.06.05		Canals and waterways
1.06.06		Landing strips and helicopter pads
1.06.07		Tunnels and bridges
1.07		**Services to and from site including wayleaves and easements**
1.07.01		Electricity
1.07.02		Gas
1.07.03		Water
1.07.04		Telephone and communications
1.07.05		Sewer
1.07.06		Pipelines (Refer to section 13.00)
1.08		**Surveys and investigations**
1.08.01		Ecological and environmental surveys
1.08.02		Geological, geotechnical, hydrographic and seismic surveys
1.08.03		Trial holes, boreholes, samples, analyses and tests
1.08.04		Site instrumental tests

1.09		**Demolition, site clearance and diversions**
1.09.01		Demolition and site clearance (see also section 02.00)
1.09.02		Diversion of roads, pipelines and services
1.09.03		Diversion of canals and waterways
1.09.04		Relocation of plant/buildings/townships etc.
1.09.05		Protection of adjoining properties
1.09.06		Removal of underground obstructions
1.10		**Ground stabilization**
1.10.01		Ground protection, compaction and/or grouting
1.10.02		Ground stabilization
1.10.03		Sink holes, subsidence and fault lines
1.10.04		Diaphragm walls
1.10.05		Suppression of vegetation
1.10.06		Preliminary drainage, dewatering or sand drains
1.11		**Fencing**
1.11.01		Permanent and temporary fencing (see also section 02.00)
1.11.02		Gates (see also section 02.00)
1.11.03		Hoardings
1.12		**Signs and illuminated boards**
1.13		**Site screening**
1.13.01		Screening embankments (see also section 02.00)
1.13.02		Tree/bush planting (see also section 02,00)
1.14		**Pre-production mine development**
1.14.01		Shafts/bores/raises/adits
1.14.02		Drives/gates/headings
1.14.03		Rooms/stopes

2		CIVIL ENGINEERING
2.01		**Excavation**
2.01.01		Site clearance, demolition
2.01.02		Excavation of topsoil including lifting turf
2.01.03		Reduce level excavation or cut and fill
2.01.04		Excavation of soft spots and filling
2.01.05		Rock removal including ripping, drilling and blasting
2.01.06		Excavation for foundations and basements
2.01.07		Excavation for existing services
2.01.08		Excavation of pits, basins, channels and ducts
2.01.09		Excavation for transport facilities and paving
2.01.10		Excavation for exposed pipe or cable tracks
2.01.11		Excavation for pipes
2.01.12		Excavation for cables
2.01.13		Diaphragm walls (see also section 01.00)
2.01.14		Dewatering (see also section 01.00)
2.01.15		Forming earth bunds and embankments
2.01.16		Sand padding (if not included elsewhere)
2.01.17		Disposal of surplus including offsite tips
2.01.18		Double handling of surplus
2.02		**Filling and shoring**
2.02.01		Selected, non-selected or imported filling
2.02.02		Bulk fill: embankments, terraces, earth bunds
2.02.03		Under structures, paving and slabs
2.02.04		Make up levels and soft spots
2.02.05		Borrow pits and quarries
2.02.06		Blinding
2.02.07		Compaction
2.02.08		Sand padding to pipes and cables
2.02.09		Temporary shoring or support work
	a)	timber
	b)	steel
	c)	scaffolding

2.03		**Geotechniques**
2.03.01		Piling
	a)	bored, cast or driven
	b)	precast concrete, prestressed and precast planks
	c)	timber
	d)	steel-isolated and interlocking sheet
	e)	cofferdams and caissons
	f)	pre-boring and disposal of surplus
	g)	enlarged bases
	h)	jetting
	i)	obstructions
	j)	permanent casings
	k)	concrete or backfill to empty bore
	l)	trim heads
	m)	excavations, concrete, reinforcement and formwork
	n)	tests: Kentledge, non-destructive, sacrificial provisions; penetration, compression, lateral, uplift; inclinometers
	o)	delays: rigs standing
2.03.02		Diaphragm walls
	a)	excavations, disposal, backfill, concrete, reinforcement
	b)	trim level of wall
	c)	joints
	d)	guide walls: excavation, disposal, backfill, concrete, reinforcement and formwork
	e)	tests
	f)	delays: rigs standing
2.03.03		Underpinning
	a)	excavation, disposal, support work, breaking out existing, backfilling concrete, formwork, reinforcement, brickwork, tanking
2.03.04		Ground and rock anchors
	a)	drill grout holes, drive injection pipes, grouting
2.03.05		gun-applied concrete
	a)	slabs, walls, beams, columns, sprayed concrete, mesh reinforced concrete and expanded metal
2.03.06		Reinforced earth
	a)	strips, planks, grids, anchors, fabrics, GRP, weldmesh, expanded metal

2.04		**Concrete supply, yard facilities, formwork and sundries**
2.04.01		Concrete supply: site mix, premix, pumped, additives: waterproof, sulphate resisting
2.04.02		Site set up: batching plant, hard standings, aggregate bins, cement silo, debagging machines, water supply, storage tanks
2.04.03		Transport: mixer trucks, dump trucks, dumpers, conveyors, monorail, pumps, chutes
2.04.04		Vibrators, vibrators, pokers, screed boards
2.04.05		Cranage
	a)	tower, fixed, rail mounted, climbing
	b)	mobile, wheel based, tracked
	c)	fork-lift trucks
2.04.06		Formwork / shuttering
	a)	timber faced, steel panels
	b)	face finish: sawn, fair, other
	c)	decking: coffered, troughed, voids, woodwool, metal profiled
	d)	vertical: beams, columns, walls
2.04.07		Reinforcement
	a)	mild steel, high yield steel, stainless steel
	b)	fabric: laps and joints
	c)	prestressed: pre-tentioned / post-tentioned
2.04.08		Precast concrete
	a)	beams, columns, slabs, portal farmes
	b)	segmental units: subways, culverts, ducts
	c)	copings, sills, cappings, lintels
	d)	kerbs, paving channels, edgings
	e)	reinforced: pre-strssed: pre-tentioned, post-tentioned
2.04.09		Sundries
	a)	expansion and construction joints
	b)	waterstops
	c)	holding-down bolts
	d)	waterproof tanking
	e)	surface treatments and finishes
	f)	chemical or acid-resistant tiling
	g)	cutting, chasing, rebating
	h)	geotextile fabrics and sheeting

	i)	grouting
2.05		**Foundations**
2.05.01		Foundations for structures
2.05.02		Retaining and basement walls
2.05.03		Foundations, paving and bunds to and around tanks
2.05.04		Precast products, including beams and sleepers
2.05.05		Foundations for plant, machinery, equipment and pipe work
2.05.06		Foundations for electrical and instrumentation installations
2.05.07		Foundations for import / export loading facilities
2.06		**Pits, basins and channels**
2.06.01		Firewater
2.06.02		Sewage treatment
2.06.03		Oil water separators
2.06.04		Slurry ponds
2.06.05		Weighbridge pits
2.06.06		Cooling water including intake / outfall structures, culverts, strainer, siphon recovery and make-up pump chambers
2.06.07		Rail unloader pits
2.07		**Ducts, etc.**
2.07.01		Cooling water culverts (if not in Section 2.1)
2.07.02		Cable ducts
2.07.03		Pipe ducts
2.07.04		Pipe culverts (under roads, etc)
2.07.05		Precast concrete cable tiles and marker posts
2.08		**Steel encasement**
2.08.01		Steel encasement
2.08.02		Fireproofing
2.09		**Transport facilities and paving**
2.09.01		Roads, turning circles and ramps
2.09.02		Paths
2.09.03		Car parks, paved areas and hard standings
2.09.04		Curbs
2.09.05		Paving under plant
2.09.06		Rail track, platforms and ancillaries (see Section 14.00)
2.09.07		Road / rail canal unloading facilities (see Section 14.00)
2.09.08		Bridges and tunnels

2.09.09		Airfield landing strips and helipads
2.09.10		Traffic signs and markings
2.10		**Marine work**
2.10.01		Cooling water intakes / outfalls, structures and culverts (if in Section 2.06.07)
2.10.02		Tidal work
2.10.03		Dredging
2.10.04		Hardfilling
2.10.05		Jetties and moorings
2.10.06		Wharves
2.10.07		Reservoirs
2.10.08		Dams
2.10.09		Breakwaters
2.10.10		Foreshore protection
2.10.11		Pontoons
2.11		**Structures**
2.11.01		Towers and silos
2.11.02		Windshields, stacks and flues
2.11.03		Tanks and pits
2.11.04		Bunds and firewalls
2.11.05		Storage for raw material or product
2.11.06		Loading/unloading structures including lifts, gantries, booms and special structures (see also section 14.00)
2.12		**Cooling towers**
2.12.01		Foundations
2.12.02		Shell
2.12.03		Collection surround
2.12.04		Internal discharge structures
2.12.05		Packing
2.12.06		Foundations for forced-draught fans
2.13		**Mining**
2.13.01		Shafts, bores and raises
2.13.02		Tunnels, rooms and stopes
2.13.03		Service tunnels
2.13.04		Storage caverns
2.13.05		Adits

2.13.06		Drives, gates and headings
2.14		**Drainage**
2.14.01		Stream or channel diversions
2.14.02		Land drainage and open ditches, lined or unlined
2.14.03		Surface water drainage
2.14.04		Sewer drainage
2.14.05		Oily water drainage
2.14.06		Other drainage
2.14.07		Crossings including river, road, rail, fence open cut or thrust
2.14.08		Pipe including fittings and coatings
2.14.09		Paddings, beds and surrounds
2.14.10		Concrete stools, thrust blocks and supports
2.14.11		Manholes, inspection chambers and gullies
2.14.12		Pits, basins and channels (see also section 2.06)
2.14.13		Septic tanks, soakaways and cesspits
2.14.14		Filter beds
2.14.15		Sedimentation chambers
2.14.16		Pumping stations
2.14.17		Valves
2.14.18		Outfalls
2.15		**Water supply**
2.15.01		Dams
2.15.02		Reservoirs
2.15.03		Stream or channel diversions
2.15.04		Leats
2.15.05		Pipework
2.15.06		Manholes and inspection chambers
2.15.07		Compensation water channels
2.15.08		Settling tanks
2.15.09		Sand filters
2.15.10		Chlorination and chemical treatment
2.15.11		Pumping stations
2.15.12		Valves
2.15.13		Intakes
2.16		**Pipework and cabling** (see also sections 6,7 and 8)
2.16.01		Water

2.16.02		Firemains and hydrants
2.16.03		Process or any other pipework below ground (see also section 6)
2.16.04		Valves and pits
2.16.05		Pipe coating
2.16.06		Pipe surrounds
2.16.07		Cable trenches, ducts, padding, tiles and markers
2.17		**Brickwork, blockwork and masonry**
2.17.01		Walls and structures
2.17.02		Stacks and flue linings
2.17.03		Ancillaries, including damp courses, ties, joint reinforcement, bonding, etc.
2.18		**Landscaping**
2.18.01		Soft landscaping
	a)	cultivating, weeding, herbicides, fertilizing, mulching
	b)	turfing, grass seeding
	c)	plants, shrubs, trees
	d)	hedges
	e)	protection
2.18.02		Hard landscaping
	a)	pavings: bricks, blocks, flags, setts, cobbles, gravel, hoggin, concrete including kerbs, edges, channels
	b)	surfaces: sports, e.g. coloured tarmacadam, sheeted, tufted, including markings and lines
.	c)	walls: retaining walls, blast walls, fences, rock-filled gabions, sight and acoustic screening
	d)	fencing and hedging: fences, hedges, security fences, gates and hoardings
	e)	site/street furniture: signs, bollards, barriers, lifting barriers, seats, benches, tables, litterbins, gritbins, dustbins and planters
	f)	equipment: sports, playground, cycle stands, clothes drying
	g)	artwork: sculptures, carvings ornamental works, flag-poles, poster hoardings, displays
2.19		**Roads**
2.19.01		Sub-base
	a)	Granular, soil cement, lean mix, hard core
2.19.02	a)	macadam: wet mix, dry bound

	b)	bitumen: open texture, dense
	c)	tarmacadam: open texture, dense
	d)	tar surface
2.19.03		Surface
	a)	cold asphalt wearing course
	b)	rolled asphalt
	c)	slurry, sealing, surface dressing bitumen spray

3		BUILDINGS INCLUDING BUILDING SERVICES
3.01		**Substructure**
3.01.01		Site investigation
3.01.02		Site clearance/demolition
3.01.03		Removal of vegetable soil
3.01.04		Reduce level excavation
3.01.05		Basement excavation
3.01.06		Soft sports and fillings
3.01.07		Sheet piling
3.01.08		Piling
3.01.09		Dewatering
3.01.10		Filling and imported filling to make up levels
3.01.11		Column bases, pile caps and ground beams
3.01.12		Strip foundations
3.01.13		Basements
3.01.14		Underpinning
3.01.15		Retaining structures
3.01.16		Rafts
3.01.17		Substructure walls
3.01.18		Floor trenches and covers
3.01.19		Underfloor drainage
3.01.20		Ground floor slab
3.02		**Superstructure**
3.02.01		Frame and encasing
3.02.02		Upper floors
3.02.03		Roofs
3.02.04		Staircases and ramps
3.02.05		Lift shafts
3.02.06		External walls
3.02.07		Windows
3.02.08		External doors
3.02.09		Flues and chimney shafts
3.02.10		Fire escapes

3.02.11		Loading bays
3.02.12		Blast or impact-resisting requirements
3.03		**Finishings**
3.03.01		Internal walls and finishes
3.03.02		Floor finishes
3.03.03		Ceiling finishes
3.03.04		Staircase finishes
3.03.05		Internal doors and screens
3.03.06		Internal decoration
3.03.07		External decoration
3.03.08		Special acoustic requirements
3.03.09		Fireproofing and insulation
3.04		**Fittings**
3.04.01		Fittings, cupboards, benches and counters
3.04.02		Furniture general
3.04.03		Special furniture (e.g. canteen/classroom)
3.04.04		Carpets and curtaining
3.04.05		Recreational equipment
3.04.06		Shutters, screens and blinds
3.05		**Services** (see also sections 6,7 and 8)
3.05.01		Sanitary fittings
3.05.02		Waste, soil and overflow pipes
3.05.03		Rainwater installation
3.05.04		Hot, cold and drinking water services
3.05.05		Heating installation
3.05.06		Gas installation
3.05.07		Electrical installation
3.05.08		Any engineering installation particular to the type of building
3.05.09		Telephone and telecommunications installations
3.05.10		Computer installation
3.05.11		Refuse disposal3.06
3.05.12		Ventilation/air conditioning installation
3.05.13		Lifts and escalators
3.05.14		Overhead cranes and rails
3.05.15		Window cleaning gear
3.05.16		Special equipment (e.g. kitchen, laboratory and laundry)

3.05.17		Security and monitoring systems
3.05.18		Fire protection (e.g. alarms, sprinklers, dry risers, hose reels and extinguishers)
3.05.19		Builder's work in connection with services
3.06		**External works**
3.06.01		Alterations to public highways
3.06.02		Roads
3.06.03		Parking areas/building
3.06.04		Paths and paved areas
3.06.05		Walling and fencing
3.06.06		Drainage
3.06.07		Lighting
3.06.08		Connection of utilities
3.06.09		Builder's work in connection with services
3.06.10		Landscaping and planting

4		STRUCTURES (Also refer to Section 2 Civil Engineering and Section 3 Buildings
4.01		**Supporting structures**
4.01.01		Structures for plant and equipment including mezzanine floors, decking
4.01.02		and any enclosing sheeting
4.01.03		Structures in support, around and access to top of plant and equipment
4.01.04		Pre-assembles units
4.01.05		Plant and equipment supports
4.01.06		Pipe racks
4.01.07		General pipe supports
4.01.08		Minor access platforms
4.01.09		Lift structures
4.01.10		Fire-fighting towers
4.01.11		Cable races
4.01.12		Unloading / loading structures
4.02		**Steelwork**
4.02.01		Supply, fabrication and erection
4.02.02		Rolled sections
4.02.03		Plates and flats
4.02.04		Hollow sections
4.02.05		Built-up box sections
4.02.06		Grillages, columns, beams and plates
4.02.07		Deck-framing and portal frames
4.02.08		Trusses, trestles, towers, bracings, purlins
4.02.09		Decking, cladding, panelling
4.02.10		Walkways, platforms
4.02.11		Bridges, gantries, balconies, ramps
4.02.12		Stairways, landings, ladders, handrails, gates, cages
4.02.13		Floor plates, gratings
4.02.14		Duct covers, frames
4.02.15		On-site welding
4.02.16		Tests
4.02.17		Surface treatments including blast cleaning, flame cleaning, galvanizing, painting
4.02.18		Ancillary items including anchor bolts, holding down-bolt assemblies,

		packing, grouting
4.03		**Timberwork**
4.03.01		Shoring
4.03.02		Columns, beams, trusses, portal frames
4.03.03		Trestles, towers, bracings, purlins
4.03.04		Decking, cladding, panelling, linings, sheeting, casings
4.03.05		Walkways, platforms, gantries, bridges
4.03.06		Stairways, landings, ladders
4.03.07		Handrails, balustrading
4.04		**Pre-cast concrete work (see Section 02.04.08 Precast Concrete)**
04.05		**Scaffolding**
4.05.01		Material: steel, galvanized, alloy, other
4.05.02		Method: supply, hire , erect, maintain, adapt, dismantle, remove
4.05.03		Location: internal, external, load bearing, below datum, in vessels
4.05.04		Type: putlog, independent, birdcage
4.05.05		Decking: boards, protection fans, safety measures
4.05.06		Ancillaries: barriers, hand and safety rails, ladders, chutes, enclosing sheeting

5		PLANT INCLUDING MACHINERY AND EQUIPMENT
5.01		**Manufacturing facilities**
5.01.01		Manufacturing plant and equipment because of the wide variation in types of product and facilities it is not possible to include a checklist, and the estimator must ascertain the requirements.
5.02		**Process plant**
5.02.01		Vessels
	a)	Reactors
	b)	Columns
	c)	Pressure vessels
	d)	Fermenters
	e)	Non-pressure vessels
	f)	Jacketed vessels
5.02.02		Vessel ancillary equipment
	a)	Agitators and supports
	b)	Internal trays
	c)	External and internal coils
	d)	Packing (Raschig rings, etc)
	e)	Distributors
5.02.03		Heat transfer including integral supports
	a)	Fixed heat exchangers
	b)	Floating heat exchangers
	c)	Finned tube air coolers
	d)	Cooling towers
5.02.04		Process displacement equipment (refer to Section 06:00 for non-process equipment)
	a)	Pumps, rotary
	b)	Pumps, reciprocating
	c)	Pumps, portable drum
	d)	Pumps, vacuum
	e)	Pumps, peristaltic
	f)	Process gas compressors
	g)	Fans
	h)	Blowers
	i)	Exhausters

	j)	Ejectors and injectors
5.02.05		Compressor ancillary equipment
	a)	Inlet filter
	b)	Inlet silencer
	c)	Discharge silencer
	d)	Pre-cooler
	e)	Inter-cooler
	f)	After cooler
	g)	Lubricating oil tank, pump and local pipe work
	h)	Lubricating oil cooler
	i)	Lubricating oil filter
5.02.06		Prime movers
	a)	Electric motors; standard, flame proof and drip proof
	b)	Gas expanders
	c)	Turbines: steam or gas
	d)	Internal combustion engines
	e)	Hydraulic turbines
	f)	Wind turbines
5.02.07		Filtration and separation
	a)	Air filters
	b)	Gas filters
	c)	Bag filters
	d)	Liquid filters
	e)	Strainers
	f)	Dust filters and precipitators
	g)	Separators
	h)	Centrifuges
	i)	Cyclones
	k)	Sieving and separating equipment
5.02.08		Heaters
	a)	Boilers
	b)	Furnaces
	c)	Ovens
	d)	Kilns
	e)	Non-fired heaters: induction RF/microwave, infra-red, etc
	f)	Stacks, flues and flares

5.02.09		Mixing equipment
	a)	Agitators
	b)	Mixing and kneading machines
	c)	Blending equipment
5.02.10		Disintegration equipment
	a)	Crushers
	b)	Grinders
	c)	Mills
5.02.11		Miscellaneous equipment
	a)	Drying equipment
	b)	Chillers and scrapers
	c)	Crystallizers
	d)	Winterization
5.03		**Electrical generation, transmission and distribution**
5.03.01		Boiler
	a)	Drum and internals
	b)	Furnace walls
	c)	Roof and enclosure
	d)	Primary super heater
	e)	Platen super heater
	f)	Final super heater
	g)	Re-heater
	h)	Attemperator
	i)	Economizer
	k)	Large-bore down comers and circulation pipe work
	l)	Boiler circulation pumps including motors
	m)	Blow down, drain and vent pipe work
	n)	Safety vessels and silencers
	o)	Drum and unit slings
	p)	Casings
5.03.02		Fuel firing
	a)	Mills
	b)	Feeders
	c)	Pulverized fuel / oil / gas burners
	d)	Pressurized air fans
	e)	Pulverized fuel piping

	f)	Stokers and chaingrates
	g)	Oil-firing lighting-up equipment including oil heaters
	h)	Burner management
	i)	Gas compressors
5.03.03		Air heaters
5.03.04		Soot blowers
5.03.05		Precipitators including rectifiers, transformers and local cabling
5.03.06		Draught plant
	a)	Forced draught fans and motors
	b)	Induced draught fans and motors
	c)	Flues
	d)	Ducts
	e)	Dampers
	f)	Local control and instrumentation
	g)	Insulation
	h)	Flue gas desulphurization
5.03.07		Main turbo alternator and associated items
	a)	Turbines: high pressure, intermediate pressure, low pressure
	b)	Valves: high pressure valves and governor gear, interceptor valves
	c)	Re-heaters
	d)	Generator including excitation system, earthing and protection
	e)	Lubrication oil system and pipe work
	f)	Generator stator cooling system
	g)	Hydrogen cooling system including storage, valves and pipe work
	h)	Carbon dioxide system including storage, valves and pipe work
	i)	Nitrogen system including storage, valves and pipe work
	j)	Condenser / dump condenser including CW valves and tubing
	k)	Feed heating system, condensate including feed regulator valves
	l)	Feed pumps including main feed pump, starting and standby feed pumps and emergency feed pumps
	m)	Local control and instrumentation (if not in Section 08:00)
5.03.08		Power station hydro turbines, pump turbines, alternators and motors
	a)	Hydro turbine including isolating and control / governing valves with
	b)	jacking and lubricating oil systems
	c)	Pump turbines including isolating and control / governing valves with
	d)	jacking and lubricating oil systems and declutching gear

	e)	Alternators including excitation systems system and ancillaries
	f)	Alternators / motors including excitation system and ancillaries
5.04		Process pipe work
5.04.01		Process pipe work (Section 06:00)

6		MECHANICAL SERVICES
6.01		**Process pipe work**
6.01.01		Carbon steel pipe work
6.01.02		Stainless steel pipe work
6.01.03		Other pipe work
6.01.04		Un-designed small-bore pipe work
6.01.05		Pipe fittings
6.01.06		Valves: motorized valves, control valves and relief valves
6.01.07		In-line equipment
6.01.08		Internal lining
6.01.09		Insulation (Also see Section 10:00)
6.01.10		External coating (Also see Section 11:00)
6.01.11		Non-destructive testing
6.01.12		Testing and cleaning
6.01.13		Trace heating (Also see Section 7:00)
6.02		**Cooling water**
6.02.01		Water source and supply including pumps and motors, and screens including backwash
6.02.02		Pre-treatment storage tanks or ponds
6.02.03		Treatment
	a)	Screens and filters
	b)	Flocculators
	c)	Settling tanks
	d)	Desalinization
	e)	Demineralization
	f)	Anti-biological, bactericidal and fungicidal
	g)	Antiscaling
	h)	De-aerators
	i)	Reverse osmosis plants
	j)	Storage, handling and dosing of treatment chemicals
6.02.04		Post-treatment storage tanks or ponds
6.02.05		Distribution
	a)	Circulating and purge pumps and motors including gearboxes
	b)	Headers, pipe work and manifolds (flow and return)
	c)	Trunk mains (flow and return)

	d)	Undersigned small-bore pipe work
	e)	Isolating valves including actuators
	f)	Internal lining
	g)	Insulation and external coating (see Section 10:00 and 11:00)
	h)	Non-destructive testing
	i)	Testing and cleaning
6.02.06		Treatment for recycling and return
	a)	Cooling towers
	b)	Spray ponds
	c)	Filters
	d)	Chlorination plant
6.03		Steam and condensate
6.03.01		Boiler plant (see Section 06:13 for boiler plant, 06:15 for fuel storage, and 06:14 for stacks and flues)
6.03.02		Steam accumulator
6.03.03		Distribution pipe work
	a)	Pipe work trunk mains
	b)	Trace heating pipe work and un-designed small-bore pipe work
	c)	Isolating, reducing and relief valves
	d)	Traps, strainers, separators and manifolds
	e)	Expansion devices
	f)	Internal lining
	g)	Insulation and external coating (see Section 10:00 and 11:00)
	h)	Non-destructive testing
	i)	Testing and cleaning
6.03.04		Condensate
	a)	Collecting and flash tanks
	b)	Pumps and motors
	c)	Pipe work
	d)	Un-designed small-bore pipe work
	e)	Headers and manifolds
	f)	Isolating valves
	g)	Condensate polishing
	h)	Insulation and external coating (see Section 10:00 and 11:00)
	i)	Non-destructive testing
	j)	Testing and cleaning
	k)	For feed heating see Section 05.03.08 on hydro turbines)

6.03.05		High pressure work: high pressure steam feeds such as that between boiler and turbine in power generation
6.04		**Process water (for relevant items see sections 06.02.01 for water source, and 06.02.02 – 06.02.04 for treatment and storage)**
6.04.01		Boiler plant (see Section 6.11 for boiler plant, 6.13 for fuel storage, and 6.12 for stacks and flues)
6.04.02		Distribution pipe work
	a)	Pumps and motors
	b)	Pipe work mains and distribution spurs
	c)	Un-designed small bore pipe work
	d)	Valves, motorized valves, control and relief valves
	e)	In-line equipment
	f)	Internal lining
	g)	Insulation and external coating (also see section 10:00 and 11:00)
	h)	Non-destructive testing
	i)	Testing and cleaning
6.05		**Potable water (Refer to section 06.02 for list of items as applicable)**
6.06		**Fire mains, spray and dosing (Ensure that below ground fire main pipe work is included in section 02.00 Civil Engineering together with storage ponds and / or intakes; for above ground pipe work see section 06.02 for list of items if applicable)**
6.06.01		Pressure storage tanks
6.06.02		Compressors including motors
6.06.03		Pumps and motors
6.06.04		Diesel pumps
6.06.05		Foam systems
6.06.06		Dry risers
6.06.07		Sprinklers and monitors
6.06.08		Detectors
6.06.09		Carbon dioxide systems
6.06.10		Halon systems
6.07		**Drainage (Ensure that below ground surface water, oily water and foul sewer drainage are included in section 02.00, civil engineering, together with separators, settlement tanks, sewerage treatment facilities and outfalls; for above-ground pipe work see section 06.02 for list of items as applicable)**

6.08		**Process effluents (solid, liquid or gaseous)**
6.08.01		Collection and storage
	a)	Solids collection system
	b)	Effluent drainage systems, sumps, ponds, interceptors and tanks
	c)	Fume intake ducts and fans
	d)	Special handling of contaminated / toxic waste
	e)	Ash handling
6.08.02		Treatment
	a)	Neutralizers
	b)	Bacteriological beds
	c)	Activated sludge beds
	d)	Oxidation / reduction
	e)	Heavy metals removal
	f)	Chemical treatment
	g)	Deodorizers
	h)	Absorbers
	i)	Chemical storage and handling including air supply for aerators
6.08.03		Separation
	a)	Flocculators
	b)	Settling tanks and beds
	c)	Drainage beds
	d)	Concentrators
	e)	Cyclones and hydro-cyclones
	f)	Filters
	g)	Grit arrestors
	h)	Electrostatic precipitators
6.08.04		Waste storage and handling
6.08.05		Disposal
	a)	Incinerators
	b)	Chimney and stacks
	c)	Dumping costs
	d)	Contaminated / toxic waste
	e)	Outfalls: sewer connections and tidal outfall control
	f)	Packaging / selling
6.08.06		Distribution
	a)	Pumps and motors
	b)	Interconnecting pipe work

	c)	Un-designed small-bore pipe work
	d)	Internal lining
	e)	Insulation and external coating (also see section 10:00 and 11:00)
	f)	Non-destructive testing
	g)	Testing and cleaning
6.09		**Gas and inert gas (Excluding air)**
6.09.01		Source
6.09.02		Unloading and storage
	a)	Handling: HP containers
	b)	Receivers
6.09.03		Generators
	a)	HP Containers
	b)	Generators
	c)	Evaporators
6.09.04		Treatment
	a)	Filters
	b)	Driers
	c)	Heaters
	d)	Refrigerators
6.09.05		After treatment and storage
	a)	HP, LP
6.09.06		Distribution
	a)	Compressors including motors, coolers and ancillaries
	b)	Headers and manifolds
	c)	Pipe work and isolating valves
	d)	Un-designed small-bore pipe work
	e)	Reducing sets
	f)	Insulation and external coating (also see section 10:00 and 11:00)
	g)	Non-destructive testing
	h)	Testing and cleaning
6.10		**Air (including compressed air)**
6.10.1		Air intake
6.10.2		Pre-treatment
	a)	Filters
	b)	Washers
	c)	Silencers
6.10.3		Compressor plant

	a)	Compressors including motors, coolers and ancillaries
6.10.4		After treatment
	a)	Filters including sterilizing filters
	b)	Scrubbers including sterilizing scrubbers
	c)	Electrostatic precipitators
	d)	Humidifiers and de-humidifiers
	e)	Heaters / coolers
6.10.5		Storage
	a)	Air receivers
	b)	Stand-by cylinders
6.10.6		Distribution
	a)	Headers and manifolds
	b)	Pipe work and isolating valves
	c)	Un-designed small-bore pipe work
	d)	Traps, separators, etc.
	e)	Reducing valves
	f)	Special outlets (, e.g. for breathing hoods, air-driven tools, etc.)
	g)	Insulation and external coating (also see section 10:00 and 11:00)
	h)	Non-destructive testing
	i)	Testing and cleaning
6.11		**Refrigeration services**
6.11.01		Storage
	a)	Refrigerant including gas cylinder handling
	b)	Cooling-medium raw materials
6.11.02		Cooling medium make-up and storage
	a)	Make-up tanks
	b)	Solid handling
	c)	Reservoir tanks
6.11.03		Refrigeration plant
	a)	Compressors: mechanical or jets
	b)	Absorbers
	c)	Freezing mixture tanks
	d)	Coolers / condensers
	e)	Receivers
	f)	Evaporators and coils
	g)	Auxiliaries including eliminators (moisture and oil)
	h)	Control gear

6.11.04		Refrigerant distribution
	a)	Pumps and motors
	b)	HP headers and manifolds
	c)	LP headers and manifolds
	d)	LP trunk mains and isolating valves
	e)	Un-designed small-bore pipe work
6.11.05		Cooling medium distribution
	a)	Pumps and motors
	b)	Headers and manifolds
	c)	Trunk mains and isolating valves
	d)	Un-designed small-bore pipe work
	e)	Insulation and external coating (also see section 10:00 and 11:00)
	f)	Non-destructive testing
	g)	Testing and cleaning
6.12		**Heating, ventilation and air conditioning**
6.12.01		Main plant
	a)	Air fans including motors
	b)	Pumps including motors
	c)	Refrigeration units
	d)	Heating units
	e)	Heat exchangers including calorifiers
	f)	Biological controls
	g)	Humidifiers
	h)	Filters
	i)	Cooling towers
	j)	Local pipe work
	k)	Drains
	l)	Storage tanks
	m)	Local duct work, silencers, intakes, exhausts
	n)	Dampers including actuators
	o)	Local controls (also see section 8.00)
	p)	Local cabling (also see section 07.00)
	q)	Insulation and external coating (also see section 10.00 and 11.00)
	r)	Control panels (also see section 8.00)
6.12.02		Duct work
	a)	Flow duct system
	b)	Return duct system

	c)	Registers
	d)	Spray / steam injectors
	e)	Dampers including actuators
	f)	Insulation and external coating (also see section 10.00 and 11.00)
6.12.03		Hot water systems
	a)	Flow and return pipe work
	b)	Manifolds
	c)	Radiators including fan assisted
	d)	Local circulating pumps including motors
	e)	Valves
	f)	Insulation and external coating (also see section 10.00 and 11.00)
	g)	Testing and cleaning
6.12.04		Direct acting and local system
	a)	Local air-conditioning units
	b)	Electric heaters
	c)	Gas / liquefied petroleum gas (LPG) / oil heaters
6.12.05		Sensors and controls (also see section 8.00)
	a)	Temperature sensors
	b)	Local area controls
	c)	Humidity sensors
	d)	Radiation sensors
6.12.06		Control system (also see section 8.00)
	a)	Remote control panels
	b)	System alarms
6.12.07		Cabling (also see section 7.00)
	a)	Power cables
	b)	Main plant cables
	c)	Damper / valve actuators cabling
	d)	Control cables
	e)	Sensor control cables
	f)	Actuator / vale control cables
	g)	Remote stations to main panel
6.12.08		Pipe work
	a)	Hot water trunk mains and distribution
	b)	Gas / LPG / oil
	c)	Refrigerant
	d)	System set-up, testing and commissioning

6.13		**Boiler plant**
6.13.01		Boilers including waste heat and electrode boilers
6.13.02		Burners
6.13.03		Stokers
6.13.04		FD and ID fans and motors
6.13.05		Super heaters
6.13.06		De-super heaters
6.13.07		Economizers
6.13.08		Air heaters and motors
6.13.09		Acid and chemical cleaning
6.13.10		Soot blowers
6.13.11		Shot cleaners
6.13.12		Grit arrestors
6.13.13		Precipitators, bag filters, etc.
6.13.14		Ash handling
6.13.15		Control gear
6.13.16		Blow down
6.13.17		Duct work and dampers including actuators
6.14		**Chimney stacks, flues and flares**
6.14.01		Lining, flues and windshields
6.14.02		Cladding
6.14.03		Anti-corrosion treatment
6.14.04		Lighting conductors
6.14.05		Warning lights
6.14.06		Flare igniters and knock-out drums
6.15		**Fuel storage and preparation**
6.15.01		Storage areas, bunkers, tanks and gas holders
6.15.02		Heating and pumping plant
6.15.03		Pulverizing plant if not with boiler
6.15.04		Solid fuel handling and weighing
6.16		**Special maintenance facilities:**
		For any item within section 06.00 as required
6.16.01		Winterization (see also section 10.00)
6.16.02		Cranes, hoists, runway beams, etc.
6.17		**Import/export loading facilities:**
		Allow for any items here only if not incorporated within section 14.00
6.17.01		Weighing devices, weighbridges, load cells, etc.

6.17.02		Cranes
6.17.03		Fork-lift trucks and specialist vehicles/attachments
6.17.04		Special rail truck handling facilities
6.17.05		Unloading and loading arms including screw unloaders
6.17.06		Barge tipplers
6.17.07		Conveyors, chutes and silos including magnetic separators, gauging, etc.
6.17.08		Vacuum or hydraulic transportation plants
6.17.09		Vacuum cleaning systems
6.17.10		Can, drum, bottling, packet filling, emptying and handling devices
6.17.11		Boom stackers, bucket wheel store/reclaim machines
6.17.12		Batching plants
6.18		**Storage**
6.18.01		Storage tanks, vessels or spheres (also see section 12.05)
6.18.02		Skimming equipment to settling tanks

7.00		ELECTRICAL SERVICES
7.01		**Extra high voltage (EHV) system (Incoming supplies above 11kV)**
7.01.01		EHV switchgear and isolators including foundations and compounds (if not separate), protective gear, metering, local controls, dedicated compressors, earthing devices, key cabinets (including contents), interlocking and exchange boxes
7.01.02		EHV cable (if not general cabling) including terminations and structure, sealing ends, watersheds, co-ordinating gaps through joints, oil/gas associated systems and connections, droppers, flexible connections and jumpers
7.01.03		EHV overhead lines including towers/poles and their foundations, cross arms, guys, insulators, surge diverters, line fuses, auto-reclosers, conductors, spacers and dampers, earth wires, droppers, flexible connections and jumpers
7.01.04		EHV transformers (EHV/HV) including foundations and compounds (if not separate), bushings and watersheds, tap changers, coolers, fans, motors, control gear, interconnecting pipework, local cubicles, oil fill, together with relay panels, protective gear and associated current transformers
7.01.05		Instrument transformers (where not supplied elsewhere) (a) voltage including, if appropriate, line couplers, line traps, support structures, local cubicles and local wiring (b) current including support structures, local cubicles and local wiring
7.01.06		Supply authority capital contribution
7.01.07		Supply authority maintenance charges
7.01.087		Charges for training and authorization for switching
.02		**High voltage (HV) system (exceeding 440 V up to 11kV)**
7.02.01		HV switchgear including foundations/support and compounds (if not separate), protective gear, metering, local controls, earthing devices, key cabinets (including contents), interlocking and exchange boxes
7.02.02		HV cables (if not general cabling) including terminations, sealing ends, watersheds, co-ordinating gaps, through joints, lugs, glands, sealing and earth links
7.02.03		HV overhead lines including towers/poles and their foundations, cross

		arms, guys, insulators, surge diverters, line fuses, auto-reclosers, conductors, dampers, earth wires, droppers, flexible connections and jumpers
7.02.04		HV transformers (HV/HV)(HV/MV) including foundations and compounds (if not separate), bushings and watersheds, tap-changers, coolers, fans, motors, control gear, interconnecting pipework, local cubicles, oil fill, together with relay panels, protective gear and associated current transformers (NB: HV/MV integral transformers are included with MV switchboards – see section 07.03.01)
7.02.05		Earthing transformers
7.02.06		Earthing resistors including fill, heaters and thermostats
07.03		**Medium voltage (MV) system (440 V and below)**
7.03.01		MV switchboard, control gear, motor starters including foundations/support and compounds (if not separate), integral transformers, busbars, outgoing circuit breakers, contactors, motor control gear, mcbs,isolators, protective gear, metering, local switchboard-mounted selector switches, control buttons, auxiliary relays, gland plates, earthing bars and links and key cabinets (including contents)
7.03.02		MV fuseboards, distribution boards and feeder pillars including case, fuseways with fuses and gland plates
7.03.03		MV outgoing circuits (a) switchboard, contractor, motor control or fuseway as appropriate (b) power cable (c) control cables (600/1000 V grade) to local control station and/or emergency stop (d) control cables (100 V grade) to local junction box (excluding junction box) to sensors, transducers, (excluding devices, detectors, etc.) (see also section 8.00 Instrumentation and controls) (e) earthing of individual circuit items if appropriate
7.04		**DC System**
7.04.01		Storage batteries including supports, acid fill, inter-cell connections, and accessories (a) 240 V (b) 110 V

		(c) 50 V (d) Other
7.04.02		Chargers including foundations/support (if not separate)
7.04.03		DC switchgear including foundations/support and compounds (if not separate) protective gear, metering, local controls, earthing devices, key cabinets (including contents) interlocking and exchange boxes and local cables
7.04.04		DC fuseboards including case, fuseways with fuses and gland plates
7.04.05		Rectifiers including foundations/support/mountings, interconnections, terminals, cooling, fuse/protection and metering
7.04.06		Inverters and uninterruptible power supplies including foundation/support/mountings, protective gear, metering, control gear, earthing devices, key cabinets (including contents) and interlocking
7.04.07		DC cables
7.04.08		Outgoing DC circuits (a) circuit breaker, contactor, fuseway or motor control device as appropriate (b) power cable (c) control cables (600/1000 V grade) to local control station and/or emergency stop (d) control cables (100 V grade) to local junction box (excluding junction box) to sensors, transducers, (excluding devices, detectors, etc.) (see also section 10.00 Instrumentation and controls) (e) earthing of individual circuit items if appropriate, emergency lighting and DC power and plant items
7.05		**Transformers:** *Transformers not included elsewhere and/or of a specialised nature including foundations and compounds (if not separate), bushings and watersheds, tap changers, coolers, fans, motors, control gear, interconnecting pipework, local cubicles, oil fill, together with relay panels, protective gear and associated current transformers*
7.05.01		Generator transformers
7.05.02		Generator unit transformers
7.05.03		Generation earth transformers including, in addition to general note above, kick fuses, grid resistors, connections to generator terminals including insulators

7.05.04		Station/auxiliary transformers
7.05.05		Instrument transformers where separately supplied for metering and/or protection including mountings
		(a) voltage transformers
		(b) current transformers
		(c) auxiliary current transformers
7.05.06		Portable transformers
7.05.07		Transformer oil-conditioning equipment
7.06		**Lighting, heating and small power**
7.06.01		Lighting equipment including fittings, light panels, luminaries, switches, starters, lamps and cabling (if not separate)
		(a) plant
		(b) buildings
		(c) street and area lighting including towers/poles, standards, columns
		(d) flood lighting including towers/poles
		(e) high bay lighting
		(f) emergency lighting
		(g) exit lighting
		(h) traffic lights and road signs
		(i) navigation lights
		(j) airfield lighting including control equipment, regulators, isolating transformers, plugs and sockets
		(k) any other listed item
7.06.02		Switchboards, fuseboards and control panels
7.06.03		Power sockets
7.06.04		Welding sockets
7.06.05		Heaters, boilers including thermostats, control switches, relays and contractors
		(a) heaters
		(b) water heaters
		(c) electrode boilers
7.06.06		Trace heating (if not part of plant controls) including heating tapes, thermostats, local connecting boxes, cabling, insulation, and finishing (if not separate)
7.06.07		Clocks including master if appropriate, slaves, outlet boxes and dedicated cabling

7.06.08		Fans including control devices
7.06.09		Security systems including power units, detectors, sensors, closed circuit TV cameras, control and display units, dedicated floodlights, bells, sirens and dedicated cabling
7.06.10		Card access system including readers, control units/computers, door/gate/turnstile control gear (including door/gate/turnstile if not included elsewhere), dedicated cabling and card issuing devices
7.06.11		Staff recording system including clocks, card readers, storage racks, control units/computers and display/output devices
7.06.12		Building monitoring system including energy, lighting, fire alarm and security systems in one package, and dedicated cabling
7.06.13		Any other listed item
7.07		**Emergency generation**
		(For main generating equipment see section 05.03)
7.07.01		Prime mover (diesel, petrol, gas, gas-turbine, hydro) including foundations, controls, local pipework
7.07.02		Alternator including excitation system, barring gear if appropriate
7.07.03		Fuel storage system
7.07.04		Lubrication system
7.07.05		Cooling systems (a) prime mover (b) oil coolers (c) storage (d) treatment
7.07.06		Neutral and earthing system
7.07.07		Synchronising, protection, automatic control
7.08		**Miscellaneous equipment**
7.08.01		Power factor correction capacitors
7.08.02		Load shedding equipment
7.09		**Cabling**
		(where not already included as part of other works)
7.09.01		Generator main connections complete, including own ventilation/cooling system, local controls and cubicles and type testing if appropriate
7.09.02		Power cables (a) EHV (b) HV: 11kV, 6.6kV and 3.3kV (c) MV 415/240 including the systems of section 09.03 and 09.06

		as appropriate
		(d) DC system including the system of section 09.04 as appropriate
7.09.03		Control and communication system cables
		(a) 600/1000 V grade (110 V system)
		(b) 100 V grade (light current systems)
		(c) screened cable
		(d) radio
		(e) special cables, thermocouple tails, etc.
		(f) other cables
7.09.04		MICC cable including olives, pots, sealing compound, beads/sleeves, saddles
7.09.05		Supports
		(a) racks
		(b) trays
		(c) conduit
		(d) trunking
		(e) transits for fireproofing
		(f) support steelwork fro above, and control stations
7.09.06		Ancillary items including gland plates, internal terminals, links jumpering, ferrules, sleeves
		(a) junction boxes
		(b) marshalling kiosks
7.09.07		Earthing system
		(a) earth mat/plates
		(b) earth rods, including driving
		(c) earth tape
		(d) trenches and cable connections
		(e) connections of plant structure to earthing system and test clamps
		(f) earthing of pylons, towers, poles, posts and fences
		(g) radio frequency earthing and system
7.09.08		Fireproofing of cable
7.09.09		Cathodic protection including anodes, pits, power supply, cabling and fittings
7.09.10		Lightning protection including conductors, tape/cable, cleats, earth electrodes and links
7.09.11		Pylons, towers, poles, posts including foundations, catenaries and all

		fittings
7.10		**Testing and commissioning** *Site testing, pre-commissioning and commissioning components and systems as required where not allowed for elsewhere*
7.11		**Civil aspects** *If civil works do not cover, account is to be taken of precast trenches, excavation, sand, cable tiles, route markers, backfill, covers, conduits, preformed ducts, sealing, weather protection and general builders work*

8.00		INSTRUMENTATION AND CONTROLS INCLUDING COMMUNICATIONS
8.01		**Computer based systems**
8.01.01		Computers including consoles/cabinets/housings, supports/mounts, power supplies, integral ventilating/cooling, dedicated inter-unit cabling, highway connections if appropriate, input/output devices, displays, data storage media, operating systems (a) main computer (b) back-up computer (c) distributed computers (d) programmable logic controllers (e) data loggers and acquisitions (f) simulators
8.01.02		Peripherals (item not included within a computer system as in section 8.02.01) (a) desk/keyboard/display unit/software loading (b) keyboards (c) VDU (d) Printers (e) Plotters (f) Recorders (g) Back-up devices/tape streamer
8.01.03		Ancillaries (a) dedicated cabling
8.01.04		Support services (where not included in other sections of the estimate) (a) heating and ventilating/cooling system (b) power supplies
8.02		**Electronic/relay based systems**
8.02.01		Equipment cubicles including cubicle, supports/mounts, cable gland plates, termination, instrument pipework, relays, interfaces, amplifiers, logic units, transmitters, receivers, all internal wiring and piping, self contained power supplies, fuses, indicating lights, self-contained ventilation cooling systems, anti-condensate heaters a) Sequence control b) Interlock c) Valve selection

		d) Alarm / annuciator e) Modulating controls
8.03		**Pneumatic Systems** (including cabinets / housings, supports / mountings, integral air compressors, local piping)
8.03.01		Actuation system a) Electrical / pneumatic converters b) Actuators
8.03.02		Self-contained systems: in addition to generic inclusion, detectors, transducers, setting devices, actuator / drive and controlling devices (valves, etc.)
8.04		**Hydraulic Systems**
8.04.01		Actuation systems including cabinets/housings, supports/mounts, integral pumps, reservoirs, tanks, piping and any converters.
8.05		**Process input devices, transducers, transmitters**
8.05.01		Transducers (and integral transmitters) including housings/mountings/supports, weatherproofing, environmental protection, internal/local wiring, internal power packs, if appropriate (a) electrical (b) pressure (c) temperature (d) level (e) flow (f) ionizing radiation, X-ray and nuclear (g) position, speed, acceleration and seismic (incl anemometer) (h) mass (i) humididty (j) chemical composition (k) optical (l) other listed items
8.05.02		Transmitters (if separate)
8.05.03		Local control stations (a) push button stations and selectors (b) emergency stops (c) multi-functions local controllers (d) supports steelwork for above

8.06		**Output devices, VDU's, indicating instruments**
8.06.01		Visual display units (when not part of complete system)
8.06.02		Mimic diagrams
8.06.03		Indicating instruments
8.06.04		Electrical integrating instruments
8.06.05		Mechanical integrating instruments
8.06.06		Recorders
8.06.07		Alarm fascias, annunciators
8.07		**Control desks and panels** *(where not included as part of a comprehensive control scheme, but including as appropriate: mounting/supports, environmental protection, weatherproofing, all internal wiring and piping, ventilation, heating, drains, terminals/connections/sockets for external cabling, pipe connectors for external piping)*
8.07.01		Desks (a) process control (b) electrical system (c) cooling water control (d) ancillary plant list
8.07.02		Control panels
8.07.03		Instrument panels
8.08		**Electronic/electrical ancillaries** *(including housing, mountings/supports, internal power packs, internal wiring, environmental protection, weatherproofing, ventilation, cooling, heating, drains and terminals/connections/sockets for external cabling)*
8.08.01		Signal conditioning equipment
8.08.02		Three term controllers
8.08.03		Additional items, e.g. special additional limit switches
8.09		**Power Packs**
8.09.01		Electrical power supply units: separate power supply units for providing AC and/or DC supplies to equipment without integral power units (a) instrument supplies (b) computer supplies (c) auxiliary supplies (d) other listed items
8.09.02		Instrument and control air compressor including base plates, housings, support/mountings, environmental protection, weatherproofing, all self-

		contained piping and wiring, drains, driers, receivers, integral instruments, terminal blocks and pipe connectors for external connections
8.09.03		Hydraulic power packs including base plates, housings, support/mountings, environmental protection, weather proofing, storage tanks, all self-contained piping and wiring, drains, integral instruments, terminal blocks and pipe connections for external connections
8.10		Fire protection *(including sensors, central and zone monitors, dedicated cabling, integral power supplies, but excluding water/foam/gas pipe work and nozzles, and excluding direct-acting sprinkler system detector)*
8.10.01		Sensors
8.10.02		Zone monitors and relays
8.10.03		Central monitor
8.11		**Remote viewing and closed circuit TV**
8.11.01		Cameras including all mountings, housings, supports, environmental protection and weatherproofing, and all facilities for swivelling, tilting and zooming
8.11.02		Monitors
8.11.03		Dedicated cabling
8.11.04		Ancillary equipment
8.11.05		Control equipment
8.11.06		Video recorders
8.11.07		Lighting gear and supplies
8.12		**Electrical actuators for valves, dampers and controllers**
8.12.01		Valve actuators (a) isolating/regulating actuators (b) modulating actuators
8.12.02		Damper actuators
8.12.03		Slave actuators for controllers
8.13		**Instrument valves, blowdown racks, impulse piping** *(including isolating and test valves and air release facilities)*
8.13.01		Instrument valves
8.13.02		Instrument blowdown racks including drain facilities to appropriate terminal point
8.13.03		Instrument impulse piping
8.13.04		Manifolds

8.14		**Communication systems**
8.14.01		PABX/PBX system including exchange equipment, main distribution frame, sockets, operators consoles, test equipment and dedicated cabling
8.14.02		Telephone instruments including acoustic enclosures if appropriate
8.14.03		Public address systems including cabinets, audio modules, amplifiers, microphones, control unit, speakers and dedicated cabling
8.14.04		Staff location/paging systems including transmitter, aerial encoders, transceivers, battery charging rack and dedicated cabling
8.14.05		Direct wire system including exchange equipment, instruments and dedicated cabling
8.14.06		Telex including machines, dedicated cabling, exchange equipment
8.14.07		Facsimile including machines, dedicated wiring and anciliaries
8.14.08		Modems and computer interfaces including equipment, dedicated wiring, power supplies and controlling software
8.14.09		Alarm/bell system including bell pushes, bells, sirens, repeaters, auto-callers, dedicated wiring and power supplies
8.14.10		Radio system including transmitter, receiver, field and/or portable receivers/transceivers, aerials, connecting radio cables, control station, battery charging racks
8.14.11		Intercom system including master station equipment, out stations and dedicated wiring
8.15		**Data communications**
8.15.01		Modems
8.15.02		Multiplexers
8.15.03		Data links
8.15.04		Dedicated cabling
8.15.05		Dedicated power supplies
8.15.06		Other interfaces
8.15.07		Control devices
8.15.08		Control software
8.15.09		External charges
8.16		**Portable instruments** *(including all cases, accessories, leads, probes, connectors, tapping devices, hoses, drains, vessels, etc.)*
8.16.01		Electrical/electronic instruments (a) volt/ammeters (b) wattmeters

		(c) electrostatic instruments
		(d) oscilloscopes
		(e) oscillator/signal generators
		(f) frequency meters
		(g) pyrometer/thermocouple
		(h) other listed items
8.16.02		Pneumatic/hydraulic instruments
		(a) pressure gauges
		(b) level gauges
		(c) flow meters
		(d) other listed items
8.17		**Applications software**
8.17.01		Software
8.17.02		Computer operator manuals
8.18		**Manuals**
8.18.01		Operating manuals
8.18.02		Maintenance manuals
8.18.03		Spare manuals
8.18.04		Testing and commissioning manuals
8.19		**Cabling** *(where not already included as part of other works)*
8.19.01		Power cables
		(a) MV 415/240 V including systems of section 7.03 and 7.06 as appropriate
		(b) DC system including system of section 07.04 as appropriate
8.19.02		Control and communication system cables
		(a) 600/1000 V grade (110 V system)
		(b) 100 V grade (light current systems)
		(c) Screened cables
		(d) Radios
		(e) Special cables
		(f) Other cables
8.19.03		MICC cables including olives, pots, sealing compound, beads/sleeves, saddles
8.19.04		Supports for pipework where appropriate as well as cables
		(a) racks
		(b) trays
		(c) conduits

		(d) support steelwork for above, and control stations
8.19.05		Ancillary items including internal terminals, links, jumpering, ferrules, sleeves
		(a) junction boxes
		(b) marshalling kiosks
		(c) transits for fireproofing
8.19.06		Earthing system
		(a) earth mat/plates
		(b) earth rods including driving
		(c) earth tape
		(d) connections of plant structure to earthing system
		(e) earthing of pylons, towers, poles, posts and fences
		(f) Radio frequency earthing and system
		(g) Trenches and cable connections
8.19.07		Fireproofing of cable
8.19.08		Pylons, towers, poles, posts including foundations, all fittings
8.20		**Instrument piping, tubing, multicore tubing and associated valves, manifolds and fittings** *(including supports, racks, trays, necessary terminal unions, joints, intermediate unions, cleats, clips, insulation, weatherproofing, trace heating, cooling and mechanical protection)*
8.20.01		Instrument air pipework
8.20.02		Process connections and assemblies, including fittings
8.20.03		Impulse pipework
8.20.04		Tubing and multi-core tubing
8.20.05		Manifolds
8.20.06		Instrument isolating valves
8.20.07		Drain, charging and other valves
8.21		**Testing and commissioning**: *site testing, pre-commissioning components and systems as required where not allowed elsewhere*
8.21.01		Component/system site testing
8.21.02		Calibration
8.21.03		Pre-commissioning
8.21.04		Commissioning
8.22		**Control valves** (*if not included with pipework)*
8.23		**Civil aspects** *(if civil works do not cover, account is to be taken of precast trenches, excavation, sand, tiles, markers, backfill, covers, conduits, ducts, sealing, weather protection and general builders work)*

9.00		REMOTE FABRICATION/PRE-ASSEMBLY FACILITIES
9.01		**Land and site development**
9.01.01		Cost of separate yard and facilities
9.01.02		Any further development required to yard and load-out facilities or access thereto
9.02		**Civil engineering**
9.02.01		Concrete bases
9.02.02		Steel supports
9.03		**Structures**
9.03.01		Additional steelwork required to modularize
9.03.02		Bracing and additional steelwork required for fabrication
9.03.03		Bolt-up sections
9.04		**Plant**
9.04.01		Additional packing plates under plant
9.05		**Mechanical Services**
9.05.01		Testing pipe in shorter sections
9.05.02		Sealing ends of pipes
9.05.03		Fabrication of spool pieces for site hook up
9.05.04		Extra welds in hook up
9.06		**Electrical services**
9.06.01		Extra testing
9.06.02		Additional junction boxes
9.06.03		Rolling up cables including additional waste in length
9.06.04		Additional jointing
9.07		**Instrumentation and controls**
9.07.01		Extra testing
9.07.02		Additional marshalling boxes
9.07.03		Rolling up cables including additional waste in length
9.07.04		Additional jointing
9.07.05		Protection of sensitive instruments (or remove and refit)
9.08		**Insulation**
9.08.01		Protection of exposed ends if insulation
9.08.02		Separate insulation over hook up welds and spool pieces
9.09		**Protective coatings**
9.09.01		Separate protective coating over hook up welds

9.10		**Engineering design**
9.10.01		Additional design costs for prefabrications or modules
9.11		**Project management and/or project charges** *(additional costs of having staff and facilities at both the worksite and fabrication yard)*
9.11.01		**Supervision and management**
9.11.02		Inspection
9.11.03		Offices and welfare facilities
9.11.04		Telephone, telex, telefax and copying machine costs
9.12		**General factors**
9.12.01		Effects of any difference in labour cost levels at fabrication yard
9.12.02		Savings constructing in permanent yard and/or in covered facilities
9.13		**Transport**
9.13.01		Any double handling of materials and transport to fabrication yard
9.13.02		Cranage and load out costs
9.13.03		Temporary load out and sea or road fastening steel
9.13.04		Sea and/or road transport
9.13.05		Heavy lift cranage and facilities at site
9.13.06		Survey, preparation of access/roads/jetties for movement of modules

10.00		INSULATION
10.00		**Type of insulation**
10.01.1		Fibre type
10.01.2		Moulded and formed insulation
10.01.3		Glass fibre
10.01.4		Mineral wool/cork
10.01.5		Polystyrene
10.01.6		Felt
10.01.7		Other specified insulation
10.02		**Heat conservation, frost and personnel protection**
10.02.01		Boiler equipment, flues and ducts
10.02.02		Heat recovery plant
10.02.03		Other plant, equipment and machinery
10.02.04		Columns
10.02.05		Vessels
10.02.06		Drums
10.02.07		Tanks
10.02.08		Pumps
10.02.09		Pipes
10.02.10		Ducts
10.02.11		Buildings
10.02.12		Voids
10.03		**Cold conservation and condensation protection**
10.03.01		Refrigeration plant
10.03.02		Cold rooms
10.03.03		Other plant, equipment and machinery
10.03.04		Pipes
10.04		**Cladding or surface finish**
10.04.01		Metal cladding to any of the foregoing
10.04.02		Fibreglass finish to walking surfaces
10.04.03		Other surface finish

11.00		PROTECTIVE COATINGS
11.01		General factors affecting cost
11.01.01		Special scaffolding
11.01.02		Surface preparation
11.01.03		Materials, application and finish
11.01.04		Type of paint including oil, epoxy, cement based, chemical resistant, fire retardant, etc.
11.01.05		Touching up prepainted items after erection
11.02		**Fire protection** *(make allowance for paint finish, cast concrete, sprayed finish, cladding or such other finish as may be required)*
11.02.01		Surface preparation and any priming and painting below finish
11.02.02		Finish to buildings: walls
11.02.03		Finish to buildings: soffits
11.02.04		Finish to buildings: structural frame
11.02.05		Finish to steel structures and supports
11.02.06		Finish to plant, equipment machinery and vessels
11.03		**Below-ground protection** *(make allowance for paint finish, tape wrapping, encasing or other protection as may be required)*
11.03.01		Underground pipework and/or joints
11.03.02		Steel structural items or piling
11.03.03		Jetties or other structures below water level
11.03.04		Waterproofing
11.04		**General painting**
11.04.01		Buildings
11.04.02		Tanks, columns, vessels and similar
11.04.03		Plant, equipment, pumps and motors
11.04.04		Steel structures including enclosing housings, platforms, pipe racks, pipe supports, stairs, ladders hand rails
11.04.05		Pipework and supports
11.04.06		Electrical and instrumentation equipment
11.04.07		Heating and ventilation ducting and equipment
11.04.08		External facilities including fencing and gates
11.04.09		Finish below insulated pipes and surfaces
11.04.10		Motifs, colour codings, bands, lettering and panels

12.00		OFFSITE FACILITIES
12.01		**Land and site development**
12.01.01		Road, rail or water access to the site
12.01.02		Services to and from the site
12.01.03		Refer to section 1.00 for other items
12.02		**Civil engineering** *(see section 2.00 for a checklist of items)*
12.02.01		Oversite excavation and filling
12.02.02		Piling
12.02.03		Foundations
12.02.04		Pits, basins and channels
12.02.05		Concrete ducts
12.02.06		Road and paving
12.02.07		Reinforcement and sundries
12.02.08		Drainage
12.02.09		Landscaping
12.03		**Buildings for shelters**
12.03.01		Boiler houses
12.03.02		Compressor houses
12.03.03		Plant buildings
12.03.04		Workshops
12.03.05		Metering buildings
12.03.06		Analyser buildings
12.03.07		Chemical stores
12.03.08		Pump houses
12.03.09		Fire station
12.03.10		Medical centre/ambulance station
12.03.11		Substations/switch houses
12.03.12		Control rooms
12.03.13		Canteen
12.03.14		Rest rooms, changing rooms and welfare buildings
12.03.15		Administration buildings
12.03.16		Pit-head buildings
12.03.17		Other buildings
12.04		**Structures**

12.05		**Plant**
12.05.01		Storage tanks and vessels
12.06		**Mechanical services**
12.06.01		Pipework
		(a) extending services, utilities and feedstock to plant
		(b) product and byproduct from plant
		(c) firewater lines
12.07		**Electrical services**
12.07.01		Extending supplies to plant
12.07.02		Supplies to all offsite plant and equipment
12.07.03		Supplies to all offsite buildings and where required to structures
12.07.04		Road and area lighting
12.07.05		Earthing
12.07.06		Lightning protection
12.07.07		Transformer compounds
12.08		**Instrumentation and controls**
12.08.01		Control panels
12.08.02		Control from panels to plant
12.08.03		Instruments to offiste plant and equipment and cabling back to panels
12.09		**Remote fabrication facilities**
12.10		**Insulation** *(heat conservation, frost and personnel protection, cold conservation and condensation protection to the following)*
12.10.01		Pipework
12.10.02		Plant, vessels and equipment
12.11		**Protective coatings** *(fire protection, below-ground protection and painting to the following)*
12.11.01		Buildings
12.11.02		Tanks, columns, vessels, plant and equipment
12.11.03		Steel structures
12.11.04		Pipework and supports

13.00		IMPORT/EXPORT PIPELINES
13.01		**General factors affecting cost**
13.01.01		Fluid transported and working pressure
13.01.02		Environmental problems
13.01.03		Terrain: waterlogged peat
13.01.04		Terrain: mountain
13.01.05		Terrain: woodland
13.01.06		Terrain: built-up areas
13.02		**Material cost**
13.02.01		Pipe
13.02.02		Thick wall pipe
13.02.03		Sleeves
13.02.04		Fittings including bends and all fittings required for block valve pigging and terminal facilities
13.02.05		Weight coating or anchors
13.02.06		Outfall nozzles
13.03		**Easement cost**
13.03.01		Type of farmland and easement payment
13.03.02		Annual easement payment
13.03.03		Loss of crop
13.03.04		Access, pipe storage and fabrication areas
13.04		**Right-of-way**
13.04.01		Clearance of right-of-way
13.04.02		Temporary fencing
13.04.03		Topsoil stripping
13.04.04		Temporary roads in bad ground
13.05		**Stringing**
13.05.01		Preparation of pipe dumps
13.05.02		Offloading in pipe dumps
13.05.03		Loading and stringing including skids
13.05.04		Cold bending
13.05.05		Provision of rollers, winches, buoyancy for offshore lines
13.06		**Trenching**
13.06.01		General trenching and backfilling
13.06.02		Trenching in bad ground or running sand
13.06.03		Dewatering

13.06.04		Trenching in rock
13.06.05		Trenching in built up areas
13.06.06		Underwater dredging, trenching, backfilling or protection
13.06.07		Sand padding
13.06.08		Imported trench backfill
13.07		**Pipelaying**
13.07.01		Welding or jointing
13.07.02		Non-destructive testing
13.07.03		Wrapping
13.07.04		Holiday detection
13.07.05		Lower and lay
13.07.06		Cathodic protection including anodes
13.07.07		Weigh coating or anchors
13.07.08		Laying of offshore live including all marine facilities, anchors and winches
13.07.09		Tie-in between offshore and onshore sections
13.08		**Crossing including additional reinstatement costs**
13.08.01		Thrust, bored or directional drilled crossings
13.08.02		Open cut: roads
13.08.03		Open cut: tracks
13.08.04		Open cut: railways
13.08.05		Open cut: water crossings
13.08.06		Open cut: ditches
13.08.07		Open cut: major services
13.08.08		Crossing other services, cattle crossings or other locations necessitating tie-ins
13.08.09		Provision for future motorways, road or river diversions, future ditch deepening or future land drainage systems
13.09		**Testing and commissioning**
13.09.01		Swabbing pig runs
13.09.02		Gauging pig runs
13.09.03		Sectional air testing
13.09.04		Provision and disposal of water
13.09.05		Water testing
13.09.06		Swabbing pig runs
13.09.07		Tie-in of test points
13.09.08		Drying

13.09.09		Guaging and/or intelligent pig runs
13.09.10		Testing material
13.10		**Reinstatement**
13.10.01		Removal of temporary roads, skids, surplus soil and general site
13.10.02		clearance
13.10.03		Ripping or loosening sub-soil
13.10.04		Making good land drainage
13.10.05		Topsoil replacement
13.10.06		Rotovating
13.10.07		Stone picking
13.10.08		Re-seeding
13.10.09		Repairs to cross fences, walls and hedges
13.10.10		Removal (or leaving in) temporary fencing
13.10.11		Permanent road reinstatement
13.10.12		Track reinstatement
13.10.13		Marker posts
13.11		**Installations**
13.11.01		Intermediate block valve installations
13.11.02		Intermediate pigging installations
13.11.03		Terminal facilities including valves and pigging facilities
13.11.04		Metering and meter proving facilities
13.11.05		Heaters
13.11.06		Compressor stations
13.11.07		Storage facilities, intermediate and at terminals
13.12		**Installation compounds**
13.12.01		Purchase/rental of land
13.12.02		Access roads
13.12.03		Compound fencing and gates
13.12.04		Compound hard surfacing
13.12.05		Civil engineering work generally
13.12.06		Mechanical work
13.12.07		Electrical and instrumentation work
13.12.08		Tree planting in screening
13.13		**Telemetering and control systems**
13.14		**Intake and outfall structures and pump houses**
13.14.01		Intake structure
13.14.02		Outfall structure

13.14.03		Pump house

14.00		**OPERATIONAL AND GENERAL SERVICES**
14.01		**Office machinery and paper handling**
14.01.01		Collection/reception
		(a) sorting
		(b) Distribution
		(c) Franking
		(d) Machines for franking, weighing, slitting and sealing
14.01.02		Telex machines, exchange lines and consumables
14.01.03		Facsimile machines, exchange lines and consumables
14.01.04		Copiers
		(a) A4 and A3 size
		(b) Sorters
		(c) Drawing reproduction machines
		(d) Consumables
14.01.05		General office machinery
		(a) typewriters
		(b) word processors
		(c) drawing boards and drafting machines
		(d) consumables
14.01.06		Computers
		(a) main frames
		(b) pc computers
		(c) computer-aided design ancillaries such as printers, plotters, monitors and back-up
		(d) consumables
14.02		**Communications**
14.02.01		Telephones
		(a) exchange and operators equipment
		(b) internal lines and dedicated cabling
		(c) external lines
		(d) instruments
		(e) answering machines
		(f) monitors and loggers
14.02.02		Radio
		(a) fixed transmitters/receivers
		(b) portable transmitters/receivers

		(c) car and personal radio telephones
		(d) staff location and bleeper systems
14.02.03		Public address
		(a) amplifier
		(b) input stations
		(c) output stations
		(d) dedicated cabling
14.02.04		Video
		(a) closed circuit tv systems
		(b) recorders
14.03		**Transport**
14.03.01		Barges, tugs, etc.
14.03.02		Shunting locomotives and rolling stock
14.03.03		Tankers, lorries
14.03.04		Cars, vans
14.03.05		Personnel transport
14.03.06		Motor cycles, cycles
14.03.07		Lift and hoist trucks
14.03.08		Mobile trucks and platforms
14.03.09		Aircraft and helicopters
14.03.10		Associated special maintenance facilities
14.04		**Maintenance facilities**
14.04.01		Site maintenance including landscape and gardening
14.04.02		Building maintenance
14.04.03		Machinery and equipment maintenance
14.04.04		Instrument maintenance
14.04.05		Electrical maintenance including lifts
14.04.06		Vehicle and aircraft maintenance
14.04.07		Cleaning facilities including vacuum cleaning and windows
14.04.08		Offloading, handling and lifting facilities
14.04.09		Cranes and portable hoists
14.04.10		Scaffolds, ladders, trestles, etc.
14.04.11		Portable equipment (e.g. concrete mixers, pumps, air-compressors, welding sets, small hand tools, etc.)
14.04.12		Associated special safety gear (e.g. goggles, welding aprons, spark proof tools, low voltage tools)
14.04.13		Spares

14.05		**Lighting**
14.05.01		Emergency lighting
14.05.02		Portable lighting
14.05.03		Warning lights
14.05.04		Traffic lights
14.05.05		Generators
14.06		**Safety and welfare**
14.06.01		Drinking water points
14.06.02		Showers and baths
14.06.03		Emergency showers and baths
14.06.04		Eyewash and first aid kits
14.06.05		Ambulances
14.06.06		Protective clothing
14.06.07		Portable equipment (resuscitators, stretchers, etc.)
14.06.08		Breathing sets, lifebelts (e.g. for tank entry)
14.06.09		Smoking areas
14.06.10		First-aid stations and equipment
14.07		**Fire services**
14.07.01		Firemains and hydrants
14.07.02		Fire applications (engines, tenders, pumps, hoses)
14.07.03		Foam and CO2 systems
14.07.04		Fire alarm systems
14.07.05		Personnel clothing and equipment
14.07.06		Safety gear (breathing equipment, ropes, etc.)
14.08		**Security**
14.08.01		Security fencing
14.08.02		Time clocks
14.08.03		Watchmen
14.08.04		Intruder alarms
14.08.05		Home office, customs and excise and similar provisions
14.08.06		Security patrols
14.09		**Weighbridge and similar provisions**
14.09.01		Weighbridge and similar provisions

15.00		TEMPORARY AND/OR COMMON SITE FACILITIES
15.01		**Utilities including distribution and outlets and, where appropriate, charges**
15.01.01		Electricity
15.01.02		Water
15.01.03		Sewage and drainage
15.01.04		Compressed air and gases
15.01.05		Telephone/telex/telefax
15.01.06		Maintenance
15.02		**Office accommodation**
15.02.01		Offices and toilets
15.02.02		Car parking
15.02.03		Cleaning and maintenance
15.02.04		Jobsite signboard
15.03		**Safety and welfare buildings**
15.03.01		Rest and changing rooms
15.03.02		Toilets and washrooms
15.03.03		Lockers and drying rooms
15.03.04		Canteen (including vending machines about site)
15.03.05		Medical suite/first aid post
15.03.06		Ambulance
15.03.07		Medical attendant
15.03.08		Smoking areas
15.03.09		Cleaning maintenance
15.04		**Stores and workshops**
15.04.01		Compound including preparation and fencing
15.04.02		Stores building
15.04.03		Stores cranage and equipment
15.04.04		Stores labour
15.04.05		Workshops
15.04.06		Cleaning and maintenance
15.05		Contractors' areas
15.05.01		Preparation
15.05.02		Fencing
15.05.03		Access to areas
15.06		**Parking and personnel transport**

15.06.01		Parking areas for workforce and staff and parking control
15.06.02		Personnel transport offsite
15.06.03		Personnel transport onsite
15.06.04		Maintenance
15.07		Site security
15.07.01		Identification pass system
15.07.02		Operation of time clocking
15.07.03		Site guards including guardhouse
15.07.04		Security floodlighting
15.07.05		Microwave and infrared systems
15.08		**Hardstandings**
15.08.01		Hardstanding to working areas and access ways
15.09		**Scaffolding**
15.09.01		Scaffolding and platforms
15.09.02		Lifts and hoists
15.10		**General site transport, cranage and plant**
15.10.01		General site transport
15.10.02		General excavators/loaders
15.10.03		Cranage including tower cranes
15.10.04		Cement storage and mixing facilities and batch plants
15.10.05		Refuelling facilities
15.10.06		Floodlighting
15.11		**Contractors providing common services to site**
15.11.01		Scaffolding
15.11.02		Cleaning
15.11.03		Catering
15.11.04		Painting
15.11.05		Office management and services
15.11.06		Cranes
15.12		**Rates**
15.12.01		Local taxation on buildings

16.00		INFRASTRUCTURE
16.01		**Facilities during construction**
16.01.01		Housing encampments
16.01.02		Medical facilities
16.01.03		Welfare and recreational facilities
16.01.04		Schooling
16.01.05		Roads and site layout
16.01.06		Harbour facilities
16.01.07		Airstrips and helipads
16.01.08		Fencing
16.01.09		Sewage systems
16.01.10		Utilities
16.01.11		Staffing of facilities
16.02		Facilities left after construction
16.02.01		Refurbishment and handover of any of the above
16.02.02		Other contributions to local or national community

17.00		**MODIFICATIONS AND ALTERATIONS TO EXISTING PLANTS**
17.01		**Demolition or removal**
17.01.01		Gas free/decommission before commencement
17.01.02		Asbestos removal
17.01.03		Plant and equipment
17.01.04		Pipework
17.01.05		Electrical, instrumentation and telecommunications cabling and apparatus
17.01.06		Structures
17.01.07		Buildings
17.01.08		Underground foundations, services and paving layouts
17.02		**New work**
17.03		**Alterations, refurbishment and updating**
17.03.01		Gas free/decommission before commencement
17.03.02		Remedial work after asbestos removal
17.03.03		Plant and equipment
17.03.04		Pipework
17.03.05		Electrical, instrumentation and telecommunications cabling and apparatus
17.03.06		Structures
17.03.07		Buildings
17.03.08		Temporary facilities to keep plant operational
17.03.09		Hoardings, barriers, dust protection, etc.
17.04		**Maintenance**
17.04.01		Maintenance painting
17.04.02		Other general maintenance work

18.00		**ENGINEERING DESIGN AND PROCUREMENT**
18.01		**Proposal engineering**
18.01.01		Proposal co-ordination
		(a) pre-bid client negotiation
		(b) prepare basic data
		(c) department liaison
		(d) co-ordinate presentation to client
		(e) post-tender negotiations
18.01.02		Estimating
		(a) engineering manhour estimate
		(b) equipment and material estimate
		(c) construction estimate
		(d) commissioning estimate
		(e) project and construction estimates
18.01.03		Planning
		(a) programme for proposal
		(b) overall project programme
		(c) manhour histograms
		(d) "S" curves for cashflow
18.01.04		Contract and legal matters
		(a) tender documents
		(b) advise on financial and cashflow requirements
		(c) preliminary contract documents
		(d) obtain ECGD and other insurance quotations
		(e) post-tender negotiations
18.01.05		Technology input
		(a) data for estimating
		(b) engineering manhour estimates
		(c) staffing programmes
		(d) material take-offs if required
		(e) input to tender documentation
18.01.06		Secretarial and clerical work
		(a) general assistance and word processing
		(b) collating and producing tender documents
18.02		**Project management**
18.02.01		Project managers

18.02.02		Project engineering
18.02.03		Project controls and accounting
18.02.04		Procurement and expediting
18.02.05		Contracts
18.02.06		Consultants and specialists
18.02.07		Secreterial and clerical work
18.02.08		Documentation
18.03		**Process engineering**
18.03.01		Basic process design
		(a) heat and material balances
		(b) process studies
		(c) utility systems
		(d) process data sheets
18.03.02		Flowsheets
		(a) process flow diagrams
		(b) engineering flow diagrams
		(c) utility flow diagrams
18.03.03		Schedules and lists
		(a) equipment lists
		(b) line lists
		(c) controls and instrument schedules
18.03.04		Safety considerations
		(a) safety guidelines
		(b) safety review
		(c) safety reports
18.03.05		Commissioning
		(a) manuals and dossiers
		(b) pre-commissioning
		(c) commissioning
18.03.06		General activities
18.04		**Civil and structural engineering**
18.04.01		Architectural design
		(a) outline schemes
		(b) development drawings
		(c) construction drawings
		(d) approval drawings
		(e) details

		(f) schedules
		(g) layouts
18.04.02		Surveys
		(a) topographical surveys
		(b) soil surveys
		(c) general surveys
		(d) pipeline surveys
18.04.03		Site development
		(a) earthworks
		(b) roads, paths and parking
		(c) railways
		(d) temporary works
		(e) general site works
		(f) fencing
18.04.04		Underground services
		(a) layouts
		(b) details
		(c) schedules
		(d) pipe anchors
18.04.05		Foundations and civils
		(a) piling layouts
		(b) foundations
		(c) bund and retaining walls
		(d) tank foundations
		(e) pipe tracks and anchors
		(f) paving
		(g) pits and basins
		(h) isolated pipe supports
		(i) bending schedules
		(j) holding-down bolt schedules
		(k) building foundations
18.04.06		Structural concrete
		(a) structures
		(b) slabs
		(c) blast walls
		(d) bridges
		(e) blast resistant buildings

		(f) bending schedules
		(g) details
18.04.07		Steelwork
		(a) structures
		(b) building frames
		(c) pre-assembled units
		(d) pre-assembled racks
		(e) pipe racks
		(f) platforms and ladders
		(g) pipe supports
		(h) schedules
18.04.08		Documentation
		(a) bills of quantity
		(b) specifications
		(c) contract documents
18.04.09		General activities
18.05		**Vessel and heat transfer engineering**
18.05.01		Basic design: storage tanks
		(a) fixed roof tanks
		(b) floating roof tanks
		(c) double skinned tanks
		(d) spherical tanks
		(e) silos, bunkers and hoppers
18.05.02		Detailed design: storage tanks
		(a) spiral stair and caged ladder
		(b) handrailing
		(c) roof walkway and interconnecting walkways
		(d) agitator fittings
		(e) coils internal and limpet
		(f) connections
		(g) support structure
		(h) double-skin cryogenic tanks
18.05.03		Basic design: pressure vessels and agitators
		(a) pressure vessels
		(b) separators
		(c) fermentors

18.05.04		Detailed design: pressure vessels and agitators
		(a) pressure vessel scantling calculations
		(b) supports
		(c) coils and jackets
		(d) agitators and supports
		(e) platform and clips
		(f) wind check and seismic loading
		(g) local loads
		(h) body flanges
		(i) internals
18.05.05		Basic and detailed design: columns and stacks
		(a) basic design calculations
		(b) body flanges
		(c) local loading
		(d) platforms, ladders and pipe clips
		(e) trays
		(f) packing
		(g) wind check and seismic loading
		(h) guy ropes
18.05.06		Basic and detailed design: heat transfer
		(a) shell and tube exchangers
		(b) tank heaters
		(c) air coolers
		(d) cooling towers
		(e) waste heat recovery units
18.05.07		Fired heaters
		(a) boilers and incinerators
		(b) furnaces, ovens and kilns
		(c) flare systems
18.05.08		Disintegration equipment
		(a) crushers
		(b) grinders
		(c) mills
18.05.09		General activities
18.06		**Machinery and mechanical engineering**
18.06.01		Rotating machinery design
		(a) gas turbines

		(b) compressors: centrifugal
		(c) compressors: reciprocating
		(d) pumps: centrifugal
		(e) pumps: reciprocating
18.06.02		Mechanical handling design
		(a) conveyors
		(b) cranes and lifting equipment
		(c) unit loading systems
		(d) weighing equipment
		(e) stacking systems
		(f) storage systems
18.06.03		Mechanical packages design
		(a) water treatment
		(b) effluent treatment
		(c) packaged units
		(d) inert gas generators
		(e) steam-raising equipment
		(f) fuel systems
		(g) filtration units
18.06.04		Services
		(a) HVAC detail specification
		(b) Heating services
		(c) Air conditioning services
		(d) plumbing
18.06.05		General activities
18.07		**Electrical engineering**
18.07.01		Specifications
		(a) general electrical
		(b) general motors
		(c) mechanical package electrical
		(d) equipment electrical
		(e) installation
18.07.02		Requisition and data sheets
		(a) main equipment requisitions
		(b) bulk material requisitions
		(c) material requisitions
		(d) basic material and material lists

		(e) calculation sheets
18.07.03		Diagrams
		(a) main single-line diagrams
		(b) loading diagram
		(c) logic sequence diagram
		(d) control schematics
		(e) lighting and small power schematics
		(f) relay grading diagram
		(g) wiring diagrams
18.07.04		Layouts
		(a) power/substation
		(b) communication
		(c) cables
		(d) cable tray
		(e) earthing
		(f) lighting and small power
		(g) fire alarm
		(h) trace heating
18.07.05		Schedules and schematics
		(a) motor schedules
		(b) terminal schedules
		(c) cable schedules
		(d) motor relay schedules
		(e) cable hook up diagrams
		(f) communication diagrams
		(g) fire alarm diagrams
18.07.06		Detail drawings
		(a) earthing details
		(b) cable installation details
		(c) cathodic protection details
		(d) trace heating isometrics
		(e) hazardous area drawing
		(f) civil requirement drawings
18.07.07		Manuals
		(a) manuals and dossiers
		(b) power study report

18.07.08		Safety
		(a) safety guidelines
		(b) safety review
		(c) final safety review
18.07.09		General activities
18.08		**Instrument engineering**
18.08.01		Conceptual design
		(a) philosophy diagrams
		(b) logic diagrams
18.08.02		Layouts
		(a) routes
		(b) instruments
		(c) control room
18.08.03		Hook-ups
		(a) selection of hook ups
		(b) process allocation
		(c) transmission allocation
		(d) produce specials
		(e) mounting and tracing
18.08.04		Indexes and schedules
		(a) instrument index
		(b) relief and safety device index
		(c) input and output schedule
		(d) equipment certification schedule
		(e) cable list
		(f) junction box schedule
18.08.05		Schematic diagrams
		(a) loop diagrams
		(b) schematics
		(c) terminal indexes
		(d) field wiring block diagrams
		(e) power distribution diagrams and schedules
		(f) earthing diagrams
		(g) instrument utilities
18.08.06		Panel design
		(a) panel layouts
		(b) panel equipment lists

		(c) rack layouts
		(d) rack equipment lists
		(e) annunciator layouts
		(f) label lists
18.08.07		Instrument specifications
		(a) FM instruments (in-line)
		(b) FM instruments (field)
		(c) Panel mounted instruments
		(d) Reliability and calculations
18.08.08		System specifications
		(a) system specifications
		(b) central control systems
		(c) programme logic control
		(d) panel and rack specifications
		(e) packaged equipment specifications
18.08.09		Material take-off
		(a) material specifications
		(b) material take-off
18.08.10		Process instrument specifications
		(a) control valves
		(b) relief valves
		(c) control instruments
		(d) indicating and alarm settings
18.08.11		Engineering line diagrams
		(a) preliminary
		(b) intermediate
		(c) final
18.08.12		Communicating equipment design
18.08.13		Packaged equipment interfaces
18.08.14		General activities
18.09		**Piping engineering**
18.09.01		Material engineering
		(a) piping and valve specifications
		(b) general piping specifications
		(c) special piping design items
		(d) flowsheet and line list review

18.09.02		Schedules
		(a) line
		(b) design
		(c) steam trap
		(d) hose coupling
18.09.03		Piping models: notional
		(a) design model
		(b) build base board
		(c) model preliminary equipment
		(d) model structure
		(e) model cable and HVAC ducts
		(f) design and model pipework
18.09.04		Piping models: detail
		(a) build base board
		(b) model equipment
		(c) model structures
		(d) model cable and HVAC ducts
		(e) model piping
		(f) final ELD/ULD model check
18.09.05		Piping studies
		(a) draft piping studies
		(b) piping site survey
18.09.06		Layouts: prepared manually
		(a) plot plans
		(b) equipment layouts
		(c) escape route layouts
		(d) HVAC layouts
		(e) Fire protection layouts
18.09.07		Layouts: computer designed
		(a) build preliminary equipment
		(b) build preliminary structure
		(c) input preliminary cable and HVAC trays
		(d) check plant model input
		(e) equipment layouts
		(f) escape layouts
		(g) HVAC layouts
		(h) fire protection layouts

		(i) HVAC layouts
18.09.08		General arrangement drawings: prepared manually
		(a) general arrangement drawings
18.09.09		General arrangement drawings: computer designed
		(a) build approved equipment
		(b) build approved structure
		(c) input catalogues/specifications/instruments
		(d) input approved cable/HVAC trays
		(e) check plant model input
		(f) input pipes
		(g) interference connection checks
		(h) drawing production
		(i) input pipe supports
		(j) module administration
18.09.10		Isometrics: prepared manually
		(a) prepare and complete isometrics
		(b) add welded attachments
18.09.11		Isometrics: computer designed
		(a) details validation
		(b) check isometric output
18.09.12		Piping stress engineering
		(a) stress piping
		(b) stress pipe supports
		(c) produce pipe stress sketches
18.09.13		Material take off: prepared manually
		(a) preliminary
		(b) intermediate
		(c) final
18.09.14		Material take off: by computer
		(a) specification input
		(b) materials control input
		(c) isometric production
18.09.15		Flow and line diagrams
		(a) process flowsheets
		(b) engineering line diagrams
		(c) utility line diagrams
		(d) HVAC flowsheets

		(e) fire protection flowsheets
18.09.16		Weight control
18.09.17		Insulation
18.09.18		General activities
18.10		**Safety engineering**
18.10.01		General safety
		(a) procedures
		(b) bid evaluation
		(c) project control procedures
		(d) safety supervision
18.10.02		Safety criteria
		(a) design safety criteria
		(b) design safety philosophy
18.10.03		Design safety
		(a) fire and gas location drawings
		(b) hazardous area drawing
		(c) layout/passive protection/firewall location
		(d) escape route drawing
		(e) safety and fire equipment drawing
		(f) safety philosophy
		(g) HVAC damper operation
		(h) Safety signs drawings
		(i) Authority approval
18.10.04		Firewater distribution
		(a) ring main calculations
		(b) water demand calculations
		(c) firewater requirement report
		(d) firewater engineering line diagram
		(e) area protection drawings
18.10.05		Safety and fire fighting equipment
		(a) deluge/sprinkler systems design
		(b) deluge/sprinkler systems calculations
18.10.06		General activities
18.11		**Quality assurance**
18.11.01		Design phase
		(a) project quality manual
		(b) project quality plans

		(c) project procedures
		(d) design quality audits
		(e) design reviews
		(f) design document review
18.11.02		Procurement phase
		(a) review requisitions
		(b) review bid evaluations
		(c) vendor quality audits
		(d) review vendor quality assurance documents
		(e) quality assurance/quality control clarification meetings
18.12		**Quality control**
18.12.01		Vendor quality control
		(a) QA/inspection: major purchases
		(b) QA/inspection: minor purchases
		(c) Inspection co-ordination
		(d) Review and approve vendor QA documents
18.13		**General activities**
18.13.01		Procurement/expediting
18.13.02		Safety reviews
18.13.03		Approve client's drawings
18.13.04		Vendor print: control and approval
18.13.05		Site liaison
18.13.06		Local authority liaison
18.13.07		Inter-departmental meetings
18.13.08		Site meetings and visits
18.13.09		Requisitions
18.13.10		Bid analysis sheets
18.13.11		As-built drawing preparation
18.13.12		Construction support
18.13.13		Weight reports
18.13.14		Final documents
18.13.15		Project close-out reports
18.13.16		Supervision
18.14		**General project costs**
18.14.01		Project office costs and expenses
		(a) overheads: head office
		(b) overheads: project office

		(c) computer time and equipment
		(d) publicity models
		(e) office space for clients personnel
		(f) overheads: photographic work and other publicity
		(g) special tests and development
18.14.02		Records and communications
		(a) preliminary documentation
		(b) collation and storage of final documentation (inclusive of test and inspection records, operating and maintenance instructions and schedules)
		(c) special printing, duplicating and collating
		(d) photocopying
		(e) reproduction of drawings
		(f) microfilming and equipment
		(g) communications: telex, fax, couriers, etc.
		(h) special photography
18.14.03		Staff costs
		(a) travel expenses
		(b) subsidence
		(c) expenses for dependants, e.g. travel, accommodation
		(d) special payment bonuses
		(e) cost of client visits
		(f) personnel training
		(g) site entertainment (special visitors)
18.14.04		Fees and charges
		(a) consultants
		(b) legal consultants
		(c) translation costs
		(d) royalties and licensing fees
		(e) licenses and permits
		(f) insurance claims assessors
		(g) research and development
		(h) agents' commissions
		(i) inspection and testing authority fees, e.g. Lloyd's
		(j) insurance premiums
		(k) insurance of materials in storage
		(l) meteorological reports

18.14.05		Finance
		(a) escalation
		(b) professional insurance bonds
		(c) performance guarantees
		(d) finance costs and bank charges
		(e) forward buying of foreign currency
		(f) export credit guarantee premiums
18.14.06		Other requirements and services
		(a) pre-commissioning spares
		(b) commissioning spares
		(c) operational spares
		(d) overseas inspection services
		(e) vendor specialists and commissioning engineers
		(f) outside buying agencies
18.14.07		Consignment costs
		(a) packaging and protection
		(b) delivery to packaging and forwarding agents
		(c) storage prior to shipment
		(d) dock dues and agents fees
		(e) freight charges
		(f) import, export duties
		(g) bond area storage costs
		(h) freight insurance
		(i) storage at port of destination
		(j) freight from port to site

19.00		PROJECT CONSTRUCTION MANAGEMENT AND PROJECT CHARGES
19.01		**Head office project management: Construction phase**
19.01.01		Engineering departmental liaison
19.01.02		Site liaison
19.01.03		Vendor liaison
19.01.04		Construction procurement
19.01.05		Freight and delivery direction
19.01.06		Expediting
19.01.07		Continuing head office management services
19.02		**Finalization of design**
19.02.01		Tails engineering (all technologies)
19.02.02		Design work required to develop contract
19.03		**Procurement**
19.03.01		Complete design phase
19.03.02		Requisition and procurement-site material requirements
19.03.03		Complete expediting
19.04		**Subcontracts**
19.04.01		Complete preparation and negotiation of subcontracts
19.04.02		Administer contract and subcontracts
19.04.03		Agreement of variations, extra works, claims, progress
19.04.04		Payment and final account settlements with subcontractors, suppliers and client
19.05		**Site management and supervision**
19.05.01		Construction manager
19.05.02		Construction engineers
19.05.03		Resident site manager
19.05.04		Cost engineers/quantity surveyors
19.05.05		Planning engineers
19.05.06		Material controllers
19.05.07		Quality assurance and quality control engineers
19.05.08		Specialist engineers and consultants
19.05.09		Industrial relations officer
19.05.10		Safety officer
19.05.11		Welding engineer
19.05.12		Buyers
19.05.13		Site accountants

19.05.14		Subcontract administrators
19.06		**Site support and services**
19.06.01		Secretarial services
19.06.02		Clerks
19.06.03		Cars/drivers
19.06.04		Fees of other consultants or agents
19.06.05		Licences and permits
19.06.06		Inspection and testing
19.06.07		Models and publicity
19.07		**Staff costs**
19.07.01		Travel and subsistence expenses
19.07.02		Expenses for dependants (e.g. travel, accommodation and schooling)
19.07.03		Training of personnel
19.08		**Site facilities**
19.08.01		Utilities, office accommodation, safety and welfare, buildings, stores, workshops, contractors' areas, parking and personnel transport, site security, hardstandings, scaffolding, general site transport, cranage, plant and local authority rates
19.09		**Records**
19.09.01		Final documentation (test and inspection records, operating and instruction manuals)
19.09.02		As-built drawings
19.10		**Overheads**
19.10.01		Head office overheads
19.10.02		Financing
19.10.03		Escalation
19.10.04		Insurances
19.10.05		Bonds and guarantees
19.10.06		Profit

20.00		OVERSEAS PROJECTS
20.01		**Design fabrication and construction**
20.01.01		Compliance with local standards, specifications, practices and quality assurance
20.02		**Consignment costs**
20.02.01		Export packaging
20.02.02		Weather protection
20.02.03		Freight to and from ports
20.02.04		Loading and offloading (land and sea freight)
20.02.05		Shipment
20.02.06		Demurrage
20.02.07		Customs delays and other delays at ports
20.02.08		Storage
20.02.09		Double handling and re-handling
20.02.10		Insurances, loss damage, etc.
20.02.11		Premiums for war zones
20.03		**Fees**
20.03.01		UK agents
20.03.02		Customs agents
20.03.03		Other agents and suppliers agents
20.03.04		Translations
20.03.05		Legal
20.04		**Commissions**
20.04.01		Bank charges including letters of credit
20.04.02		Export credit guarantee
20.04.03		Buying
20.04.04		Consulate charges
20.04.05		Gratuities
20.04.06		Local agent
20.05		**Taxes and dues**
20.05.01		Import duties and port dues
20.05.02		Transmission taxes
20.05.03		Other local taxes
20.06		**Local territory costs**
20.06.01		Legislation: use of local labour and materials
20.06.02		Quality, cost and availability of local labour, plant and materials

20.06.03		Compliance with local regulations
20.06.04		Local trade practices, demarcation, etc.
20.06.05		Availability and suitability of local roads, utilities and housing
20.07		**Expatriate staff and labour**
20.07.01		Overseas allowances
20.07.02		Accommodation
20.07.03		Air fares and travel expenses
20.07.04		Leave
20.07.05		Local income tax
20.07.06		Work permits, visas and licenses
20.07.07		Site welfare facilities
20.07.08		Schooling
20.07.09		Medical expenses
20.07.10		Local transport
20.08		**Additional costs**
20.08.01		Higher level of initial spares
20.08.02		Higher level of construction, commissioning and operational spares
20.08.03		Extra cost of emergency freight
20.09		**Other risks**
20.09.01		Major economic dislocation
20.09.02		Payment: currency and place of payment
20.09.03		Risks not covered by any export credit guarantee
20.09.04		Settlement of disputes

21.00		COMMISSIONING, INITIAL OPERATION AND TRAINING
21.01		**Commissioning**
21.01.01		Ascertaining extent of work (i.e. assistance only to client)
21.01.02		Specialist engineers and operators
21.01.03		Commissioning equipment
21.01.04		Vendor's commissioning engineers and operators
21.01.05		Power supplies and consumables
21.01.06		Remedial work including special studies, investigations and redesigning as required
21.02		**Initial operation**
21.02.01		Start up costs
21.02.02		Operators and labour
21.02.03		Power supplies, consumables and raw materials
21.02.04		Working alongside and training clients operators
21.03		**Training**
21.03.01		Training clients staff: classroom
21.03.02		Training clients staff: during operation
21.03.03		Translations of manuals to local language
21.04		**Final clean up and making good**

22.00		PROVISIONAL SUMS, CONTINGENCIES AND ESCALATION
22.01		**Provisional and prime cost (PC) sums to be included on direction of client**
22.02		**Provisional and prime cost (PC) sums included by estimator**
22.03		**Contingency sums to be included on direction of client**
22.04		**Contingency allowance included by estimator which may include any of the following items**
22.04.01		Inclement weather
22.04.02		Industrial relations problems
22.04.03		Delays by others
22.04.04		Historical growth factor which may include design development and construction changes, unforeseen items, additional work, variations and claims
22.04.05		Quality of information and data and estimate accuracy
22.04.06		Risk
22.05		**Escalation and inflation in the following**
22.05.01		Engineering and design
22.05.02		Construction and labour
22.05.03		Construction plant
22.05.04		Construction materials
22.05.05		Site overheads and management
22.05.06		Fixed price element
22.05.07		Differences between actual increase and any reimbursement by any index
22.05.08		Market forces

Key:

1	Material	Type of material used
2	Labour	Availibility of labour and skills at the time of construction
3	Eng design	Complexity of the engineering design
4	Cur econ c	Current economic conditions - at the time of construction
5	Cur econ f	Current economic factors - at the time of construction
6	Scope def	Level of scope definition at the time of construction
7	Rework	Amount of rework that was done on the project
8	S change	Level of scope changes that occurred
9	Weather	General weather conditions at the time of construction
10	Access	Access to the site when project was excecuted
11	P size	Size of the project
12	P cond	General conditions at the time of construction
13	Complex	Complexity of the project in general
14	Repitition	Level of repitition work that occurred

Project 1

Year of construction 2005
